## 1 Introduction

This reference manual describes the functions provided by the Red Hat "newlib" version of the standard ANSI C library. This document is not intended as an overview or a tutorial for the C library. Each library function is listed with a synopsis of its use, a brief description, return values (including error handling), and portability issues.

Some of the library functions depend on support from the underlying operating system and may not be available on every platform. For embedded systems in particular, many of these underlying operating system services may not be available or may not be fully functional. The specific operating system subroutines required for a particular library function are listed in the "Portability" section of the function description. See Chapter 12 [Syscalls], page 301, for a description of the relevant operating system calls.

# 2 Standard Utility Functions ('stdlib.h')

This chapter groups utility functions useful in a variety of programs. The corresponding declarations are in the header file 'stdlib.h'.

# 2.1 \_Exit—end program execution with no cleanup processing

## **Synopsis**

```
#include <stdlib.h>
void _Exit(int code);
```

## Description

Use \_Exit to return control from a program to the host operating environment. Use the argument *code* to pass an exit status to the operating environment: two particular values, EXIT\_SUCCESS and EXIT\_FAILURE, are defined in 'stdlib.h' to indicate success or failure in a portable fashion.

\_Exit differs from exit in that it does not run any application-defined cleanup functions registered with atexit and it does not clean up files and streams. It is identical to \_exit.

#### Returns

\_Exit does not return to its caller.

## **Portability**

\_Exit is defined by the C99 standard.

Supporting OS subroutines required: \_exit.

# 2.2 a641, 164a—convert between radix-64 ASCII string and long

## **Synopsis**

```
#include <stdlib.h>
long a641(const char *input);
char *164a(long input);
```

#### Description

Conversion is performed between long and radix-64 characters. The 164a routine transforms up to 32 bits of input value starting from least significant bits to the most significant bits. The input value is split up into a maximum of 5 groups of 6 bits and possibly one group of 2 bits (bits 31 and 30).

Each group of 6 bits forms a value from 0–63 which is translated into a character as follows:

- 0 = '.'
- 1 = '/'
- 2-11 = 0 to '9'
- 12-37 = 'A' to 'Z'
- 38-63 = 'a' to 'z'

When the remaining bits are zero or all bits have been translated, a null terminator is appended to the string. An input value of 0 results in the empty string.

The a641 function performs the reverse translation. Each character is used to generate a 6-bit value for up to 30 bits and then a 2-bit value to complete a 32-bit result. The null terminator means that the remaining digits are 0. An empty input string or NULL string results in 0L. An invalid string results in undefined behavior. If the size of a long is greater than 32 bits, the result is sign-extended.

#### Returns

164a returns a null-terminated string of 0 to 6 characters. a641 returns the 32-bit translated value from the input character string.

#### **Portability**

164a and a641 are non-ANSI and are defined by the Single Unix Specification.

Supporting OS subroutines required: None.

## 2.3 abort—abnormal termination of a program

## Synopsis

```
#include <stdlib.h>
void abort(void);
```

## Description

Use abort to signal that your program has detected a condition it cannot deal with. Normally, abort ends your program's execution.

Before terminating your program, abort raises the exception SIGABRT (using 'raise(SIGABRT)'). If you have used signal to register an exception handler for this condition, that handler has the opportunity to retain control, thereby avoiding program termination.

In this implementation, abort does not perform any stream- or file-related cleanup (the host environment may do so; if not, you can arrange for your program to do its own cleanup with a SIGABRT exception handler).

#### Returns

abort does not return to its caller.

## **Portability**

ANSI C requires abort.

Supporting OS subroutines required: \_exit and optionally, write.

## 2.4 abs—integer absolute value (magnitude)

## **Synopsis**

```
#include <stdlib.h>
int abs(int i);
```

## Description

abs returns |x|, the absolute value of i (also called the magnitude of i). That is, if i is negative, the result is the opposite of i, but if i is nonnegative the result is i.

The similar function labs uses and returns long rather than int values.

### Returns

The result is a nonnegative integer.

## Portability

abs is ANSI.

## 2.5 assert—macro for debugging diagnostics

## **Synopsis**

```
#include <assert.h>
void assert(int expression);
```

## Description

Use this macro to embed debuggging diagnostic statements in your programs. The argument expression should be an expression which evaluates to true (nonzero) when your program is working as you intended.

When expression evaluates to false (zero), assert calls abort, after first printing a message showing what failed and where:

```
Assertion failed: expression, file filename, line lineno, function: func
```

If the name of the current function is not known (for example, when using a C89 compiler that does not understand \_\_func\_\_), the function location is omitted.

The macro is defined to permit you to turn off all uses of assert at compile time by defining NDEBUG as a preprocessor variable. If you do this, the assert macro expands to (void(0))

#### Returns

assert does not return a value.

## **Portability**

The assert macro is required by ANSI, as is the behavior when NDEBUG is defined.

Supporting OS subroutines required (only if enabled): close, fstat, getpid, isatty, kill, lseek, read, sbrk, write.

# 2.6 atexit—request execution of functions at program exit Synopsis

```
#include <stdlib.h>
int atexit (void (*function)(void));
```

## Description

You can use atexit to enroll functions in a list of functions that will be called when your program terminates normally. The argument is a pointer to a user-defined function (which must not require arguments and must not return a result).

The functions are kept in a LIFO stack; that is, the last function enrolled by atexit will be the first to execute when your program exits.

There is no built-in limit to the number of functions you can enroll in this list; however, after every group of 32 functions is enrolled, atexit will call malloc to get space for the next part of the list. The initial list of 32 functions is statically allocated, so you can always count on at least that many slots available.

#### Returns

atexit returns 0 if it succeeds in enrolling your function, -1 if it fails (possible only if no space was available for malloc to extend the list of functions).

### Portability

atexit is required by the ANSI standard, which also specifies that implementations must support enrolling at least 32 functions.

## 2.7 atof, atoff—string to double or float

## **Synopsis**

```
#include <stdlib.h>
double atof(const char *s);
float atoff(const char *s);
```

#### Description

atof converts the initial portion of a string to a double. atoff converts the initial portion of a string to a float.

The functions parse the character string s, locating a substring which can be converted to a floating-point value. The substring must match the format:

```
[+|-] digits [.] [digits] [(e|E)[+|-] digits]
```

The substring converted is the longest initial fragment of s that has the expected format, beginning with the first non-whitespace character. The substring is empty if str is empty, consists entirely of whitespace, or if the first non-whitespace character is something other than +, -, ., or a digit.

atof(s) is implemented as strtod(s, NULL). atoff(s) is implemented as strtof(s, NULL).

#### Returns

atof returns the converted substring value, if any, as a double; or 0.0, if no conversion could be performed. If the correct value is out of the range of representable values, plus or minus HUGE\_VAL is returned, and ERANGE is stored in errno. If the correct value would cause underflow, 0.0 is returned and ERANGE is stored in errno.

atoff obeys the same rules as atof, except that it returns a float.

#### **Portability**

atof is ANSI C. atof, atoi, and atol are subsumed by strod and strol, but are used extensively in existing code. These functions are less reliable, but may be faster if the argument is verified to be in a valid range.

## 2.8 atoi, atol—string to integer

## **Synopsis**

```
#include <stdlib.h>
int atoi(const char *s);
long atol(const char *s);
int _atoi_r(struct _reent *ptr, const char *s);
long _atol_r(struct _reent *ptr, const char *s);
```

#### Description

atoi converts the initial portion of a string to an int. atol converts the initial portion of a string to a long.

atoi(s) is implemented as (int)strtol(s, NULL, 10). atol(s) is implemented as strtol(s, NULL, 10).

\_atoi\_r and \_atol\_r are reentrant versions of atoi and atol respectively, passing the reentrancy struct pointer.

### Returns

The functions return the converted value, if any. If no conversion was made, 0 is returned.

## **Portability**

atoi, atol are ANSI.

## 2.9 atoll—convert a string to a long long integer

## Synopsis

```
#include <stdlib.h>
long long atoll(const char *str);
long long _atoll_r(struct _reent *ptr, const char *str);
```

## Description

The function atoll converts the initial portion of the string pointed to by \*str to a type long long. A call to atoll(str) in this implementation is equivalent to strtoll(str, (char \*\*)NULL, 10) including behavior on error.

The alternate function \_atoll\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The converted value.

## **Portability**

atoll is ISO 9899 (C99) and POSIX 1003.1-2001 compatable.

## 2.10 bsearch—binary search

## **Synopsis**

## Description

bsearch searches an array beginning at base for any element that matches key, using binary search. nmemb is the element count of the array; size is the size of each element.

The array must be sorted in ascending order with respect to the comparison function *compar* (which you supply as the last argument of bsearch).

You must define the comparison function (\*compar) to have two arguments; its result must be negative if the first argument is less than the second, zero if the two arguments match, and positive if the first argument is greater than the second (where "less than" and "greater than" refer to whatever arbitrary ordering is appropriate).

#### Returns

Returns a pointer to an element of array that matches key. If more than one matching element is available, the result may point to any of them.

## **Portability**

bsearch is ANSI.

## 2.11 calloc—allocate space for arrays

## Synopsis

```
#include <stdlib.h>
void *calloc(size_t n, size_t s);
void *_calloc_r(void *reent, size_t n, size_t s);
```

## Description

Use calloc to request a block of memory sufficient to hold an array of n elements, each of which has size s.

The memory allocated by calloc comes out of the same memory pool used by malloc, but the memory block is initialized to all zero bytes. (To avoid the overhead of initializing the space, use malloc instead.)

The alternate function \_calloc\_r is reentrant. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

If successful, a pointer to the newly allocated space.

If unsuccessful, NULL.

## **Portability**

calloc is ANSI.

## 2.12 div—divide two integers

## **Synopsis**

```
#include <stdlib.h>
div_t div(int n, int d);
```

## Description

Divide n/d, returning quotient and remainder as two integers in a structure div\_t.

#### Returns

The result is represented with the structure

```
typedef struct
{
  int quot;
  int rem;
} div_t;
```

where the quot field represents the quotient, and rem the remainder. For nonzero d, if 'r = div(n,d);' then n equals 'r.rem + d\*r.quot'.

To divide long rather than int values, use the similar function ldiv.

## **Portability**

div is ANSI.

# 2.13 ecvt, ecvtf, fcvt, fcvtf—double or float to string Synopsis

```
#include <stdlib.h>
char *ecvt(double val, int chars, int *decpt, int *sgn);
char *ecvtf(float val, int chars, int *decpt, int *sgn);
char *fcvt(double val, int decimals,
   int *decpt, int *sgn);
char *fcvtf(float val, int decimals,
   int *decpt, int *sgn);
```

#### Description

ecvt and fcvt produce (null-terminated) strings of digits representating the double number val. ecvtf and fcvtf produce the corresponding character representations of float numbers.

(The stdlib functions ecvtbuf and fcvtbuf are reentrant versions of ecvt and fcvt.)

The only difference between ecvt and fcvt is the interpretation of the second argument (chars or decimals). For ecvt, the second argument chars specifies the total number of characters to write (which is also the number of significant digits in the formatted string, since these two functions write only digits). For fcvt, the second argument decimals specifies the number of characters to write after the decimal point; all digits for the integer part of val are always included.

Since ecvt and fcvt write only digits in the output string, they record the location of the decimal point in \*decpt, and the sign of the number in \*sgn. After formatting a number, \*decpt contains the number of digits to the left of the decimal point. \*sgn contains 0 if the number is positive, and 1 if it is negative.

#### Returns

All four functions return a pointer to the new string containing a character representation of val.

#### **Portability**

None of these functions are ANSI C.

## 2.14 gvcvt, gcvtf—format double or float as string

## **Synopsis**

```
#include <stdlib.h>
char *gcvt(double val, int precision, char *buf);
char *gcvtf(float val, int precision, char *buf);
```

## Description

gcvt writes a fully formatted number as a null-terminated string in the buffer \*buf. gdvtf produces corresponding character representations of float numbers.

gcvt uses the same rules as the printf format '%.precisiong'—only negative values are signed (with '-'), and either exponential or ordinary decimal-fraction format is chosen depending on the number of significant digits (specified by precision).

#### Returns

The result is a pointer to the formatted representation of val (the same as the argument buf).

#### **Portability**

Neither function is ANSI C.

## 2.15 ecvtbuf, fcvtbuf—double or float to string

## Synopsis

```
#include <stdio.h>
char *ecvtbuf(double val, int chars, int *decpt,
    int *sgn, char *buf);
char *fcvtbuf(double val, int decimals, int *decpt,
    int *sgn, char *buf);
```

#### Description

ecvtbuf and fcvtbuf produce (null-terminated) strings of digits representating the double number val.

The only difference between ecvtbuf and fcvtbuf is the interpretation of the second argument (chars or decimals). For ecvtbuf, the second argument chars specifies the total number of characters to write (which is also the number of significant digits in the formatted string, since these two functions write only digits). For fcvtbuf, the second argument decimals specifies the number of characters to write after the decimal point; all digits for the integer part of val are always included.

Since ecvtbuf and fcvtbuf write only digits in the output string, they record the location of the decimal point in \*decpt, and the sign of the number in \*sgn. After formatting a number, \*decpt contains the number of digits to the left of the decimal point. \*sgn contains 0 if the number is positive, and 1 if it is negative. For both functions, you supply a pointer buf to an area of memory to hold the converted string.

#### Returns

Both functions return a pointer to buf, the string containing a character representation of val.

## Portability

Neither function is ANSI C.

## 2.16 \_\_env\_lock, \_\_env\_unlock—lock environ variable

## **Synopsis**

```
#include <envlock.h>
void __env_lock (struct _reent *reent);
void __env_unlock (struct _reent *reent);
```

### Description

The setenv family of routines call these functions when they need to modify the environ variable. The version of these routines supplied in the library use the lock API defined in sys/lock.h. If multiple threads of execution can call setenv, or if setenv can be called reentrantly, then you need to define your own versions of these functions in order to safely lock the memory pool during a call. If you do not, the memory pool may become corrupted. A call to setenv may call \_\_env\_lock recursively; that is, the sequence of calls may go \_\_env\_lock, \_\_env\_unlock, \_\_env\_unlock. Any implementation of these routines must be careful to avoid causing a thread to wait for a lock that it already holds.

## 2.17 exit—end program execution

## **Synopsis**

```
#include <stdlib.h>
void exit(int code);
```

## Description

Use exit to return control from a program to the host operating environment. Use the argument *code* to pass an exit status to the operating environment: two particular values, EXIT\_SUCCESS and EXIT\_FAILURE, are defined in 'stdlib.h' to indicate success or failure in a portable fashion.

exit does two kinds of cleanup before ending execution of your program. First, it calls all application-defined cleanup functions you have enrolled with atexit. Second, files and streams are cleaned up: any pending output is delivered to the host system, each open file or stream is closed, and files created by tmpfile are deleted.

#### Returns

exit does not return to its caller.

### **Portability**

ANSI C requires exit, and specifies that EXIT\_SUCCESS and EXIT\_FAILURE must be defined. Supporting OS subroutines required: \_exit.

## 2.18 getenv—look up environment variable

## **Synopsis**

```
#include <stdlib.h>
char *getenv(const char *name);
```

## Description

getenv searches the list of environment variable names and values (using the global pointer "char \*\*environ") for a variable whose name matches the string at name. If a variable name matches, getenv returns a pointer to the associated value.

#### Returns

A pointer to the (string) value of the environment variable, or NULL if there is no such environment variable.

## **Portability**

getenv is ANSI, but the rules for properly forming names of environment variables vary from one system to another.

getenv requires a global pointer environ.

## 2.19 labs—long integer absolute value

## **Synopsis**

```
#include <stdlib.h>
long labs(long i);
```

## Description

labs returns |x|, the absolute value of i (also called the magnitude of i). That is, if i is negative, the result is the opposite of i, but if i is nonnegative the result is i.

The similar function abs uses and returns int rather than long values.

### Returns

The result is a nonnegative long integer.

## Portability

labs is ANSI.

## 2.20 ldiv—divide two long integers

## **Synopsis**

```
#include <stdlib.h>
ldiv_t ldiv(long n, long d);
```

## Description

Divide n/d, returning quotient and remainder as two long integers in a structure ldiv\_t.

#### Returns

The result is represented with the structure

```
typedef struct
{
  long quot;
  long rem;
} ldiv_t;
```

where the quot field represents the quotient, and rem the remainder. For nonzero d, if 'r = 1 div(n,d);' then n = 1 equals ' r.rem + d\*r.quot'.

To divide int rather than long values, use the similar function div.

## **Portability**

ldiv is ANSI.

# 2.21 llabs—compute the absolute value of an long long integer.

## **Synopsis**

```
#include <stdlib.h>
long long llabs(long long j);
```

## Description

The llabs function computes the absolute value of the long long integer argument j (also called the magnitude of j).

The similar function labs uses and returns long rather than long long values.

### Returns

A nonnegative long long integer.

## Portability

llabs is ISO 9899 (C99) compatable.

## 2.22 lldiv—divide two long long integers

## **Synopsis**

```
#include <stdlib.h>
lldiv_t lldiv(long long n, long long d);
```

## Description

Divide n/d, returning quotient and remainder as two long long integers in a structure  $lldiv_t$ .

#### Returns

The result is represented with the structure

```
typedef struct
{
  long long quot;
  long long rem;
} lldiv_t;
```

where the quot field represents the quotient, and rem the remainder. For nonzero d, if 'r = 1 div(n,d);' then n = 1 equals ' r.rem + d\*r.quot'.

To divide long rather than long long values, use the similar function ldiv.

## **Portability**

lldiv is ISO 9899 (C99) compatable.

## 2.23 malloc, realloc, free—manage memory

## **Synopsis**

```
#include <stdlib.h>
void *malloc(size_t nbytes);
void *realloc(void *aptr, size_t nbytes);
void *reallocf(void *aptr, size_t nbytes);
void free(void *aptr);
void *memalign(size_t align, size_t nbytes);
size_t malloc_usable_size(void *aptr);
void *_malloc_r(void *reent, size_t nbytes);
void *_realloc_r(void *reent,
   void *aptr, size_t nbytes);
void *_reallocf_r(void *reent,
    void *aptr, size_t nbytes);
void _free_r(void *reent, void *aptr);
void *_memalign_r(void *reent,
    size_t align, size_t nbytes);
size_t _malloc_usable_size_r(void *reent, void *aptr);
```

#### Description

These functions manage a pool of system memory.

Use malloc to request allocation of an object with at least *nbytes* bytes of storage available. If the space is available, malloc returns a pointer to a newly allocated block as its result.

If you already have a block of storage allocated by malloc, but you no longer need all the space allocated to it, you can make it smaller by calling realloc with both the object pointer and the new desired size as arguments. realloc guarantees that the contents of the smaller object match the beginning of the original object.

Similarly, if you need more space for an object, use realloc to request the larger size; again, realloc guarantees that the beginning of the new, larger object matches the contents of the original object.

When you no longer need an object originally allocated by malloc or realloc (or the related function calloc), return it to the memory storage pool by calling free with the address of the object as the argument. You can also use realloc for this purpose by calling it with 0 as the *nbytes* argument.

The reallocf function behaves just like realloc except if the function is required to allocate new storage and this fails. In this case reallocf will free the original object passed in whereas realloc will not.

The memalign function returns a block of size *nbytes* aligned to a *align* boundary. The *align* argument must be a power of two.

The malloc\_usable\_size function takes a pointer to a block allocated by malloc. It returns the amount of space that is available in the block. This may or may not be more than the size requested from malloc, due to alignment or minimum size constraints.

The alternate functions <code>\_malloc\_r</code>, <code>\_realloc\_r</code>, <code>\_reallocf\_r</code>, <code>\_free\_r</code>, <code>\_memalign\_r</code>, and <code>\_malloc\_usable\_size\_r</code> are reentrant versions. The extra argument <code>reent</code> is a pointer to a reentrancy structure.

If you have multiple threads of execution which may call any of these routines, or if any of these routines may be called reentrantly, then you must provide implementations of the <code>\_\_malloc\_lock</code> and <code>\_\_malloc\_unlock</code> functions for your system. See the documentation for those functions.

These functions operate by calling the function <code>\_sbrk\_r</code> or <code>sbrk</code>, which allocates space. You may need to provide one of these functions for your system. <code>\_sbrk\_r</code> is called with a positive value to allocate more space, and with a negative value to release previously allocated space if it is no longer required. See Section 12.1 [Stubs], page 301.

#### Returns

malloc returns a pointer to the newly allocated space, if successful; otherwise it returns NULL. If your application needs to generate empty objects, you may use malloc(0) for this purpose.

realloc returns a pointer to the new block of memory, or NULL if a new block could not be allocated. NULL is also the result when you use 'realloc(aptr,0)' (which has the same effect as 'free(aptr)'). You should always check the result of realloc; successful reallocation is not guaranteed even when you request a smaller object.

free does not return a result.

memalign returns a pointer to the newly allocated space.

malloc\_usable\_size returns the usable size.

#### **Portability**

malloc, realloc, and free are specified by the ANSI C standard, but other conforming implementations of malloc may behave differently when *nbytes* is zero.

memalign is part of SVR4.

malloc\_usable\_size is not portable.

Supporting OS subroutines required: sbrk.

## 2.24 mallinfo, malloc\_stats, mallopt—malloc support

## **Synopsis**

```
#include <malloc.h>
struct mallinfo mallinfo(void);
void malloc_stats(void);
int mallopt(int parameter, value);

struct mallinfo _mallinfo_r(void *reent);
void _malloc_stats_r(void *reent);
int _mallopt_r(void *reent, int parameter, value);
```

## Description

mallinfo returns a structure describing the current state of memory allocation. The structure is defined in malloc.h. The following fields are defined: arena is the total amount of space in the heap; ordblks is the number of chunks which are not in use; uordblks is the total amount of space allocated by malloc; fordblks is the total amount of space not in use; keepcost is the size of the top most memory block.

malloc\_stats print some statistics about memory allocation on standard error.

mallopt takes a parameter and a value. The parameters are defined in malloc.h, and may be one of the following: M\_TRIM\_THRESHOLD sets the maximum amount of unused space in the top most block before releasing it back to the system in free (the space is released by calling \_sbrk\_r with a negative argument); M\_TOP\_PAD is the amount of padding to allocate whenever \_sbrk\_r is called to allocate more space.

The alternate functions \_mallinfo\_r, \_malloc\_stats\_r, and \_mallopt\_r are reentrant versions. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

mallinfo returns a mallinfo structure. The structure is defined in malloc.h.

malloc\_stats does not return a result.

mallopt returns zero if the parameter could not be set, or non-zero if it could be set.

#### **Portability**

mallinfo and mallopt are provided by SVR4, but mallopt takes different parameters on different systems. malloc\_stats is not portable.

## 2.25 \_\_malloc\_lock, \_\_malloc\_unlock—lock malloc pool

## **Synopsis**

```
#include <malloc.h>
void __malloc_lock (struct _reent *reent);
void __malloc_unlock (struct _reent *reent);
```

### Description

The malloc family of routines call these functions when they need to lock the memory pool. The version of these routines supplied in the library use the lock API defined in sys/lock.h. If multiple threads of execution can call malloc, or if malloc can be called reentrantly, then you need to define your own versions of these functions in order to safely lock the memory pool during a call. If you do not, the memory pool may become corrupted.

A call to malloc may call \_\_malloc\_lock recursively; that is, the sequence of calls may go \_\_ malloc\_lock, \_\_malloc\_unlock, \_\_malloc\_unlock. Any implementation of these routines must be careful to avoid causing a thread to wait for a lock that it already holds.

## 2.26 mblen—minimal multibyte length function

## **Synopsis**

```
#include <stdlib.h>
int mblen(const char *s, size_t n);
```

## Description

When \_MB\_CAPABLE is not defined, this is a minimal ANSI-conforming implementation of mblen. In this case, the only "multi-byte character sequences" recognized are single bytes, and thus 1 is returned unless s is the null pointer or has a length of 0 or is the empty string.

When \_MB\_CAPABLE is defined, this routine calls \_mbtowc\_r to perform the conversion, passing a state variable to allow state dependent decoding. The result is based on the locale setting which may be restricted to a defined set of locales.

#### Returns

This implementation of mblen returns 0 if s is NULL or the empty string; it returns 1 if not \_MB\_CAPABLE or the character is a single-byte character; it returns -1 if the multi-byte character is invalid; otherwise it returns the number of bytes in the multibyte character.

### **Portability**

mblen is required in the ANSI C standard. However, the precise effects vary with the locale. mblen requires no supporting OS subroutines.

# 2.27 mbsrtowcs, mbsnrtowcs—convert a character string to a wide-character string

## **Synopsis**

```
#include <wchar.h>
size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len,
    mbstate_t *ps);

#include <wchar.h>
size_t _mbsrtowcs_r(struct _reent *ptr, wchar_t *dst,
    const char **src, size_t len,
    mbstate_t *ps);

#include <wchar.h>
size_t mbsnrtowcs(wchar_t *dst, const char **src,
    size_t nms, size_t len, mbstate_t *ps);

#include <wchar.h>
size_t _mbsnrtowcs_r(struct _reent *ptr, wchar_t *dst,
    const char **src, size_t nms,
    size_t len, mbstate_t *ps);
```

#### Description

The mbsrtowcs function converts a sequence of multibyte characters pointed to indirectly by src into a sequence of corresponding wide characters and stores at most len of them in the wchar\_t array pointed to by dst, until it encounters a terminating null character ('\0'). If dst is NULL, no characters are stored.

If dst is not NULL, the pointer pointed to by src is updated to point to the character after the one that conversion stopped at. If conversion stops because a null character is encountered, \*src is set to NULL.

The mbstate\_t argument, ps, is used to keep track of the shift state. If it is NULL, mbsrtowcs uses an internal, static mbstate\_t object, which is initialized to the initial conversion state at program startup.

The mbsnrtowcs function behaves identically to mbsrtowcs, except that conversion stops after reading at most nms bytes from the buffer pointed to by src.

#### Returns

The mbsrtowcs and mbsnrtowcs functions return the number of wide characters stored in the array pointed to by dst if successful, otherwise it returns (size\_t)-1.

#### **Portability**

mbsrtowcs is defined by the C99 standard. mbsnrtowcs is defined by the POSIX.1-2008 standard.

# 2.28 mbstowcs—minimal multibyte string to wide char converter

## **Synopsis**

```
#include <stdlib.h>
int mbstowcs(wchar_t *pwc, const char *s, size_t n);
```

## Description

When \_MB\_CAPABLE is not defined, this is a minimal ANSI-conforming implementation of mbstowcs. In this case, the only "multi-byte character sequences" recognized are single bytes, and they are "converted" to wide-char versions simply by byte extension.

When \_MB\_CAPABLE is defined, this routine calls \_mbstowcs\_r to perform the conversion, passing a state variable to allow state dependent decoding. The result is based on the locale setting which may be restricted to a defined set of locales.

#### Returns

This implementation of mbstowcs returns 0 if s is NULL or is the empty string; it returns -1 if \_MB\_CAPABLE and one of the multi-byte characters is invalid or incomplete; otherwise it returns the minimum of: n or the number of multi-byte characters in s plus 1 (to compensate for the nul character). If the return value is -1, the state of the pwc string is indeterminate. If the input has a length of 0, the output string will be modified to contain a wchar\_t nul terminator.

### **Portability**

mbstowcs is required in the ANSI C standard. However, the precise effects vary with the locale.

mbstowcs requires no supporting OS subroutines.

## 2.29 mbtowc—minimal multibyte to wide char converter

## **Synopsis**

```
#include <stdlib.h>
int mbtowc(wchar_t *pwc, const char *s, size_t n);
```

## Description

When  $\_$ MB $\_$ CAPABLE is not defined, this is a minimal ANSI-conforming implementation of mbtowc. In this case, only "multi-byte character sequences" recognized are single bytes, and they are "converted" to themselves. Each call to mbtowc copies one character from \*s to \*pwc, unless s is a null pointer. The argument n is ignored.

When \_MB\_CAPABLE is defined, this routine calls \_mbtowc\_r to perform the conversion, passing a state variable to allow state dependent decoding. The result is based on the locale setting which may be restricted to a defined set of locales.

#### Returns

This implementation of mbtowc returns 0 if s is NULL or is the empty string; it returns 1 if not \_MB\_CAPABLE or the character is a single-byte character; it returns -1 if n is 0 or the multi-byte character is invalid; otherwise it returns the number of bytes in the multibyte character. If the return value is -1, no changes are made to the pwc output string. If the input is the empty string, a wchar\_t nul is placed in the output string and 0 is returned. If the input has a length of 0, no changes are made to the pwc output string.

#### Portability

mbtowc is required in the ANSI C standard. However, the precise effects vary with the locale

mbtowc requires no supporting OS subroutines.

# 2.30 on\_exit—request execution of function with argument at program exit

## **Synopsis**

```
#include <stdlib.h>
int on_exit (void (*function)(int, void *), void *arg);
```

## Description

You can use on\_exit to enroll functions in a list of functions that will be called when your program terminates normally. The argument is a pointer to a user-defined function which takes two arguments. The first is the status code passed to exit and the second argument is of type pointer to void. The function must not return a result. The value of arg is registered and passed as the argument to function.

The functions are kept in a LIFO stack; that is, the last function enrolled by atexit or on\_exit will be the first to execute when your program exits. You can intermix functions using atexit and on\_exit.

There is no built-in limit to the number of functions you can enroll in this list; however, after every group of 32 functions is enrolled, atexit/on\_exit will call malloc to get space for the next part of the list. The initial list of 32 functions is statically allocated, so you can always count on at least that many slots available.

### Returns

on\_exit returns 0 if it succeeds in enrolling your function, -1 if it fails (possible only if no space was available for malloc to extend the list of functions).

### Portability

on\_exit is a non-standard glibc extension Supporting OS subroutines required: None

# 2.31 qsort—sort an array

## **Synopsis**

```
#include <stdlib.h>
void qsort(void *base, size_t nmemb, size_t size,
   int (*compar)(const void *, const void *);
```

#### Description

qsort sorts an array (beginning at base) of nmemb objects. size describes the size of each element of the array.

You must supply a pointer to a comparison function, using the argument shown as *compar*. (This permits sorting objects of unknown properties.) Define the comparison function to accept two arguments, each a pointer to an element of the array starting at *base*. The result of (\*compar) must be negative if the first argument is less than the second, zero if the two arguments match, and positive if the first argument is greater than the second (where "less than" and "greater than" refer to whatever arbitrary ordering is appropriate).

The array is sorted in place; that is, when **qsort** returns, the array elements beginning at base have been reordered.

#### Returns

qsort does not return a result.

## **Portability**

qsort is required by ANSI (without specifying the sorting algorithm).

# 2.32 rand, srand—pseudo-random numbers

## **Synopsis**

```
#include <stdlib.h>
int rand(void);
void srand(unsigned int seed);
int rand_r(unsigned int *seed);
```

## Description

rand returns a different integer each time it is called; each integer is chosen by an algorithm designed to be unpredictable, so that you can use rand when you require a random number. The algorithm depends on a static variable called the "random seed"; starting with a given value of the random seed always produces the same sequence of numbers in successive calls to rand.

You can set the random seed using srand; it does nothing beyond storing its argument in the static variable used by rand. You can exploit this to make the pseudo-random sequence less predictable, if you wish, by using some other unpredictable value (often the least significant parts of a time-varying value) as the random seed before beginning a sequence of calls to rand; or, if you wish to ensure (for example, while debugging) that successive runs of your program use the same "random" numbers, you can use srand to set the same random seed at the outset.

#### Returns

rand returns the next pseudo-random integer in sequence; it is a number between 0 and RAND\_MAX (inclusive).

srand does not return a result.

#### Portability

rand is required by ANSI, but the algorithm for pseudo-random number generation is not specified; therefore, even if you use the same random seed, you cannot expect the same sequence of results on two different systems.

rand requires no supporting OS subroutines.

# 2.33 rand48, drand48, erand48, 1rand48, nrand48, mrand48, jrand48, srand48, seed48, 1cong48—pseudo-random number generators and initialization routines

## Synopsis

```
#include <stdlib.h>
double drand48(void);
double erand48(unsigned short xseed[3]);
long lrand48(void);
long nrand48(unsigned short xseed[3]);
long mrand48(void);
long jrand48(unsigned short xseed[3]);
void srand48(long seed);
unsigned short *seed48(unsigned short xseed[3]);
void lcong48(unsigned short p[7]);
```

#### Description

The rand48 family of functions generates pseudo-random numbers using a linear congruential algorithm working on integers 48 bits in size. The particular formula employed is  $r(n+1) = (a * r(n) + c) \mod m$  where the default values are for the multiplicand a = 0xfdeece66d = 25214903917 and the addend c = 0xb = 11. The modulo is always fixed at m = 2 \*\* 48. r(n) is called the seed of the random number generator.

For all the six generator routines described next, the first computational step is to perform a single iteration of the algorithm.

drand48 and erand48 return values of type double. The full 48 bits of r(n+1) are loaded into the mantissa of the returned value, with the exponent set such that the values produced lie in the interval [0.0, 1.0].

lrand48 and nrand48 return values of type long in the range  $[0, 2^{**}31-1]$ . The high-order (31) bits of r(n+1) are loaded into the lower bits of the returned value, with the topmost (sign) bit set to zero.

mrand48 and jrand48 return values of type long in the range  $[-2^{**}31, 2^{**}31-1]$ . The high-order (32) bits of r(n+1) are loaded into the returned value.

drand48, 1rand48, and mrand48 use an internal buffer to store r(n). For these functions the initial value of r(0) = 0x1234abcd330e = 20017429951246.

On the other hand, erand48, nrand48, and jrand48 use a user-supplied buffer to store the seed r(n), which consists of an array of 3 shorts, where the zeroth member holds the least significant bits.

All functions share the same multiplicand and addend.

srand48 is used to initialize the internal buffer r(n) of drand48, 1rand48, and mrand48 such that the 32 bits of the seed value are copied into the upper 32 bits of r(n), with the lower 16 bits of r(n) arbitrarily being set to 0x330e. Additionally, the constant multiplicand and addend of the algorithm are reset to the default values given above.

seed48 also initializes the internal buffer r(n) of drand48, 1rand48, and mrand48, but here all 48 bits of the seed can be specified in an array of 3 shorts, where the zeroth member specifies the lowest bits. Again, the constant multiplicand and addend of the algorithm are reset to the default values given above. seed48 returns a pointer to an array of 3 shorts

which contains the old seed. This array is statically allocated, thus its contents are lost after each new call to seed48.

Finally, lcong48 allows full control over the multiplicand and addend used in drand48, erand48, lrand48, nrand48, mrand48, and jrand48, and the seed used in drand48, lrand48, and mrand48. An array of 7 shorts is passed as parameter; the first three shorts are used to initialize the seed; the second three are used to initialize the multiplicand; and the last short is used to initialize the addend. It is thus not possible to use values greater than 0xffff as the addend.

Note that all three methods of seeding the random number generator always also set the multiplicand and addend for any of the six generator calls.

For a more powerful random number generator, see random.

### Portability

SUS requires these functions.

# 2.34 strtod, strtof—string to double or float

## **Synopsis**

#### Description

The function **strtod** parses the character string *str*, producing a substring which can be converted to a double value. The substring converted is the longest initial subsequence of *str*, beginning with the first non-whitespace character, that has one of these formats:

The substring contains no characters if str is empty, consists entirely of whitespace, or if the first non-whitespace character is something other than +, -, ., or a digit, and cannot be parsed as infinity or NaN. If the platform does not support NaN, then NaN is treated as an empty substring. If the substring is empty, no conversion is done, and the value of str is stored in \*tail. Otherwise, the substring is converted, and a pointer to the final string (which will contain at least the terminating null character of str) is stored in \*tail. If you want no assignment to \*tail, pass a null pointer as tail. strtof is identical to strtod except for its return type.

This implementation returns the nearest machine number to the input decimal string. Ties are broken by using the IEEE round-even rule. However, strtof is currently subject to double rounding errors.

The alternate function \_strtod\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

strtod returns the converted substring value, if any. If no conversion could be performed, 0 is returned. If the correct value is out of the range of representable values, plus or minus HUGE\_VAL is returned, and ERANGE is stored in errno. If the correct value would cause underflow, 0 is returned and ERANGE is stored in errno.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 2.35 strtol—string to long

## **Synopsis**

### Description

The function strtol converts the string \*s to a long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of characters resembling an integer in the radix specified by base; and a trailing portion consisting of zero or more unparseable characters, and always including the terminating null character. Then, it attempts to convert the subject string into a long and returns the result.

If the value of base is 0, the subject string is expected to look like a normal C integer constant: an optional sign, a possible '0x' indicating a hexadecimal base, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of letters and digits representing an integer in the radix specified by base, with an optional plus or minus sign. The letters a-z (or, equivalently, A-Z) are used to signify values from 10 to 35; only letters whose ascribed values are less than base are permitted. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible letter or digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, strtol attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. If the subject string begins with a minus sign, the value is negated. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (or not in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_strtol\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

strtol returns the converted value, if any. If no conversion was made, 0 is returned. strtol returns LONG\_MAX or LONG\_MIN if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

strtol is ANSI.

# 2.36 strtoll—string to long long

## **Synopsis**

```
#include <stdlib.h>
long long strtoll(const char *s, char **ptr,int base);
long long _strtoll_r(void *reent,
        const char *s, char **ptr,int base);
```

# Description

The function strtoll converts the string \*s to a long long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of characters resembling an integer in the radix specified by base; and a trailing portion consisting of zero or more unparseable characters, and always including the terminating null character. Then, it attempts to convert the subject string into a long long and returns the result.

If the value of base is 0, the subject string is expected to look like a normal C integer constant: an optional sign, a possible '0x' indicating a hexadecimal base, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of letters and digits representing an integer in the radix specified by base, with an optional plus or minus sign. The letters a—z (or, equivalently, A—Z) are used to signify values from 10 to 35; only letters whose ascribed values are less than base are permitted. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible letter or digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, strtoll attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. If the subject string begins with a minus sign, the value is negated. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (or not in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_strtoll\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

strtoll returns the converted value, if any. If no conversion was made, 0 is returned. strtoll returns LONG\_LONG\_MAX or LONG\_LONG\_MIN if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

strtoll is ANSI.

# 2.37 strtoul—string to unsigned long

# **Synopsis**

```
#include <stdlib.h>
unsigned long strtoul(const char *s, char **ptr,
    int base);
unsigned long _strtoul_r(void *reent, const char *s,
    char **ptr, int base);
```

#### Description

The function strtoul converts the string \*s to an unsigned long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of the digits meaningful in the radix specified by base (for example, 0 through 7 if the value of base is 8); and a trailing portion consisting of one or more unparseable characters, which always includes the terminating null character. Then, it attempts to convert the subject string into an unsigned long integer, and returns the result.

If the value of base is zero, the subject string is expected to look like a normal C integer constant (save that no optional sign is permitted): a possible 0x indicating hexadecimal radix, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of digits (which may include letters, depending on the base) representing an integer in the radix specified by base. The letters a-z (or A-Z) are used as digits valued from 10 to 35. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, strtoul attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (that is, if \*s does not start with a substring in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_strtoul\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

strtoul returns the converted value, if any. If no conversion was made, 0 is returned. strtoul returns ULONG\_MAX if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

strtoul is ANSI.

strtoul requires no supporting OS subroutines.

# 2.38 strtoull—string to unsigned long long

# **Synopsis**

```
#include <stdlib.h>
unsigned long long strtoull(const char *s, char **ptr,
    int base);
unsigned long long _strtoull_r(void *reent, const char *s,
    char **ptr, int base);
```

#### Description

The function strtoull converts the string \*s to an unsigned long long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of the digits meaningful in the radix specified by base (for example, 0 through 7 if the value of base is 8); and a trailing portion consisting of one or more unparseable characters, which always includes the terminating null character. Then, it attempts to convert the subject string into an unsigned long long integer, and returns the result.

If the value of base is zero, the subject string is expected to look like a normal C integer constant (save that no optional sign is permitted): a possible 0x indicating hexadecimal radix, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of digits (which may include letters, depending on the base) representing an integer in the radix specified by base. The letters a-z (or A-Z) are used as digits valued from 10 to 35. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, strtoull attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (that is, if \*s does not start with a substring in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_strtoull\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

strtoull returns the converted value, if any. If no conversion was made, 0 is returned. strtoull returns ULONG\_LONG\_MAX if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

strtoull is ANSI.

strtoull requires no supporting OS subroutines.

# 2.39 wcsrtombs, wcsnrtombs—convert a wide-character string to a character string

## **Synopsis**

```
#include <wchar.h>
size_t wcsrtombs(char *dst, const wchar_t **src, size_t len,
    mbstate_t *ps);

#include <wchar.h>
size_t _wcsrtombs_r(struct _reent *ptr, char *dst,
    const wchar_t **src, size_t len,
    mbstate_t *ps);

#include <wchar.h>
size_t wcsnrtombs(char *dst, const wchar_t **src,
    size_t nwc, size_t len, mbstate_t *ps);

#include <wchar.h>
size_t _wcsnrtombs_r(struct _reent *ptr, char *dst,
    const wchar_t **src, size_t nwc,
    size_t len, mbstate_t *ps);
```

#### Description

The wcsrtombs function converts a string of wide characters indirectly pointed to by src to a corresponding multibyte character string stored in the array pointed to by dst. No more than len bytes are written to dst.

If dst > is NULL, no characters are stored.

If dst> is not NULL, the pointer pointed to by src is updated to point to the character after the one that conversion stopped at. If conversion stops because a null character is encountered, \*src is set to NULL.

The mbstate\_t argument, ps, is used to keep track of the shift state. If it is NULL, wcsrtombs uses an internal, static mbstate\_t object, which is initialized to the initial conversion state at program startup.

The wcsnrtombs function behaves identically to wcsrtombs, except that conversion stops after reading at most nwc characters from the buffer pointed to by src.

#### Returns

The wcsrtombs and wcsnrtombs functions return the number of bytes stored in the array pointed to by dst (not including any terminating null), if successful, otherwise it returns (size\_t)-1.

#### Portability

wcsrtombs is defined by C99 standard. wcsnrtombs is defined by the POSIX.1-2008 standard.

# 2.40 wcstof—wide char string to double or float

## **Synopsis**

#### Description

The function wcstod parses the wide character string str, producing a substring which can be converted to a double value. The substring converted is the longest initial subsequence of str, beginning with the first non-whitespace character, that has one of these formats:

The substring contains no characters if str is empty, consists entirely of whitespace, or if the first non-whitespace character is something other than +, -, ., or a digit, and cannot be parsed as infinity or NaN. If the platform does not support NaN, then NaN is treated as an empty substring. If the substring is empty, no conversion is done, and the value of str is stored in \*tail. Otherwise, the substring is converted, and a pointer to the final string (which will contain at least the terminating null character of str) is stored in \*tail. If you want no assignment to \*tail, pass a null pointer as tail. wcstof is identical to wcstod except for its return type.

This implementation returns the nearest machine number to the input decimal string. Ties are broken by using the IEEE round-even rule. However, wcstof is currently subject to double rounding errors.

The alternate functions \_wcstod\_r and \_wcstof\_r are reentrant versions of wcstod and wcstof, respectively. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

Return the converted substring value, if any. If no conversion could be performed, 0 is returned. If the correct value is out of the range of representable values, plus or minus HUGE\_VAL is returned, and ERANGE is stored in errno. If the correct value would cause underflow, 0 is returned and ERANGE is stored in errno.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 2.41 wcstol—wide string to long

## **Synopsis**

# Description

The function wcstol converts the wide string \*s to a long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of characters resembling an integer in the radix specified by base; and a trailing portion consisting of zero or more unparseable characters, and always including the terminating null character. Then, it attempts to convert the subject string into a long and returns the result.

If the value of base is 0, the subject string is expected to look like a normal C integer constant: an optional sign, a possible '0x' indicating a hexadecimal base, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of letters and digits representing an integer in the radix specified by base, with an optional plus or minus sign. The letters a-z (or, equivalently, A-Z) are used to signify values from 10 to 35; only letters whose ascribed values are less than base are permitted. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible letter or digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, wcstol attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. If the subject string begins with a minus sign, the value is negated. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (or not in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_wcstol\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

wcstol returns the converted value, if any. If no conversion was made, 0 is returned. wcstol returns LONG\_MAX or LONG\_MIN if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

wcstol is ANSI.

# 2.42 wcstoll—wide string to long long

## **Synopsis**

# Description

The function wcstoll converts the wide string \*s to a long long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of characters resembling an integer in the radix specified by base; and a trailing portion consisting of zero or more unparseable characters, and always including the terminating null character. Then, it attempts to convert the subject string into a long long and returns the result.

If the value of base is 0, the subject string is expected to look like a normal C integer constant: an optional sign, a possible '0x' indicating a hexadecimal base, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of letters and digits representing an integer in the radix specified by base, with an optional plus or minus sign. The letters a—z (or, equivalently, A—Z) are used to signify values from 10 to 35; only letters whose ascribed values are less than base are permitted. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible letter or digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, wcstoll attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. If the subject string begins with a minus sign, the value is negated. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (or not in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_wcstoll\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

wcstoll returns the converted value, if any. If no conversion was made, 0 is returned. wcstoll returns LONG\_LONG\_MAX or LONG\_LONG\_MIN if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

wcstoll is ANSI.

# 2.43 wcstoul—wide string to unsigned long

# Synopsis

```
#include <wchar.h>
unsigned long wcstoul(const wchar_t *s, wchar_t **ptr,
    int base);
unsigned long _wcstoul_r(void *reent, const wchar_t *s,
    wchar_t **ptr, int base);
```

#### Description

The function wcstoul converts the wide string \*s to an unsigned long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of the digits meaningful in the radix specified by base (for example, 0 through 7 if the value of base is 8); and a trailing portion consisting of one or more unparseable characters, which always includes the terminating null character. Then, it attempts to convert the subject string into an unsigned long integer, and returns the result.

If the value of base is zero, the subject string is expected to look like a normal C integer constant (save that no optional sign is permitted): a possible 0x indicating hexadecimal radix, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of digits (which may include letters, depending on the base) representing an integer in the radix specified by base. The letters a-z (or A-Z) are used as digits valued from 10 to 35. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, wcstoul attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (that is, if \*s does not start with a substring in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_wcstoul\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

wcstoul returns the converted value, if any. If no conversion was made, O is returned. wcstoul returns ULONG\_MAX if the magnitude of the converted value is too large, and sets errno to ERANGE.

#### **Portability**

wcstoul is ANSI.

wcstoul requires no supporting OS subroutines.

# 2.44 wcstoull—wide string to unsigned long long

# **Synopsis**

```
#include <wchar.h>
unsigned long long wcstoull(const wchar_t *s, wchar_t **ptr,
    int base);
unsigned long long _wcstoull_r(void *reent, const wchar_t *s,
    wchar_t **ptr, int base);
```

## Description

The function wcstoull converts the wide string \*s to an unsigned long long. First, it breaks down the string into three parts: leading whitespace, which is ignored; a subject string consisting of the digits meaningful in the radix specified by base (for example, 0 through 7 if the value of base is 8); and a trailing portion consisting of one or more unparseable characters, which always includes the terminating null character. Then, it attempts to convert the subject string into an unsigned long long integer, and returns the result

If the value of base is zero, the subject string is expected to look like a normal C integer constant: an optional sign (+ or -), a possible 0x indicating hexadecimal radix or a possible <0> indicating octal radix, and a number. If base is between 2 and 36, the expected form of the subject is a sequence of digits (which may include letters, depending on the base) representing an integer in the radix specified by base. The letters a-z (or A-Z) are used as digits valued from 10 to 35. If base is 16, a leading 0x is permitted.

The subject sequence is the longest initial sequence of the input string that has the expected form, starting with the first non-whitespace character. If the string is empty or consists entirely of whitespace, or if the first non-whitespace character is not a permissible digit, the subject string is empty.

If the subject string is acceptable, and the value of base is zero, wcstoull attempts to determine the radix from the input string. A string with a leading 0x is treated as a hexadecimal value; a string with a leading 0 and no x is treated as octal; all other strings are treated as decimal. If base is between 2 and 36, it is used as the conversion radix, as described above. Finally, a pointer to the first character past the converted subject string is stored in ptr, if ptr is not NULL.

If the subject string is empty (that is, if \*s does not start with a substring in acceptable form), no conversion is performed and the value of s is stored in ptr (if ptr is not NULL).

The alternate function \_wcstoull\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

wcstoull returns 0 and sets errno to EINVAL if the value of base is not supported. wcstoull returns the converted value, if any. If no conversion was made, 0 is returned.

wcstoull returns ULLONG\_MAX if the magnitude of the converted value is too large, and sets errno to ERANGE.

# Portability

wcstoull is ANSI.

wcstoull requires no supporting OS subroutines.

# 2.45 system—execute command string

# **Synopsis**

```
#include <stdlib.h>
int system(char *s);
int _system_r(void *reent, char *s);
```

# Description

Use system to pass a command string \*s to /bin/sh on your system, and wait for it to finish executing.

Use "system(NULL)" to test whether your system has /bin/sh available.

The alternate function \_system\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

system(NULL) returns a non-zero value if /bin/sh is available, and 0 if it is not.

With a command argument, the result of system is the exit status returned by /bin/sh.

## **Portability**

ANSI C requires system, but leaves the nature and effects of a command processor undefined. ANSI C does, however, specify that system(NULL) return zero or nonzero to report on the existence of a command processor.

POSIX.2 requires system, and requires that it invoke a sh. Where sh is found is left unspecified.

Supporting OS subroutines required: \_exit, \_execve, \_fork\_r, \_wait\_r.

# 2.46 wcstombs—minimal wide char string to multibyte string converter

# **Synopsis**

```
#include <stdlib.h>
size_t wcstombs(char *s, const wchar_t *pwc, size_t n);
```

## Description

When \_MB\_CAPABLE is not defined, this is a minimal ANSI-conforming implementation of wcstombs. In this case, all wide-characters are expected to represent single bytes and so are converted simply by casting to char.

When \_MB\_CAPABLE is defined, this routine calls \_wcstombs\_r to perform the conversion, passing a state variable to allow state dependent decoding. The result is based on the locale setting which may be restricted to a defined set of locales.

#### Returns

This implementation of wcstombs returns 0 if s is NULL or is the empty string; it returns -1 if \_MB\_CAPABLE and one of the wide-char characters does not represent a valid multi-byte character; otherwise it returns the minimum of: n or the number of bytes that are transferred to s, not including the nul terminator.

If the return value is -1, the state of the pwc string is indeterminate. If the input has a length of 0, the output string will be modified to contain a wchar\_t nul terminator if n > 0.

## **Portability**

wcstombs is required in the ANSI C standard. However, the precise effects vary with the locale.

wcstombs requires no supporting OS subroutines.

# 2.47 wctomb—minimal wide char to multibyte converter

## **Synopsis**

```
#include <stdlib.h>
int wctomb(char *s, wchar_t wchar);
```

## Description

When \_MB\_CAPABLE is not defined, this is a minimal ANSI-conforming implementation of wctomb. The only "wide characters" recognized are single bytes, and they are "converted" to themselves.

When \_MB\_CAPABLE is defined, this routine calls \_wctomb\_r to perform the conversion, passing a state variable to allow state dependent decoding. The result is based on the locale setting which may be restricted to a defined set of locales.

Each call to wctomb modifies \*s unless s is a null pointer or \_MB\_CAPABLE is defined and wchar is invalid.

#### Returns

This implementation of wctomb returns 0 if s is NULL; it returns -1 if  $_{\rm -MB\_CAPABLE}$  is enabled and the wchar is not a valid multi-byte character, it returns 1 if  $_{\rm -MB\_CAPABLE}$  is not defined or the wchar is in reality a single byte character, otherwise it returns the number of bytes in the multi-byte character.

## **Portability**

wctomb is required in the ANSI C standard. However, the precise effects vary with the locale.

wctomb requires no supporting OS subroutines.

# 3 Character Type Macros and Functions ('ctype.h')

This chapter groups macros (which are also available as subroutines) to classify characters into several categories (alphabetic, numeric, control characters, whitespace, and so on), or to perform simple character mappings.

The header file 'ctype.h' defines the macros.

# 3.1 isalnum—alphanumeric character predicate

# **Synopsis**

```
#include <ctype.h>
int isalnum(int c);
```

# Description

isalnum is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for alphabetic or numeric ASCII characters, and 0 for other arguments. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isalnum'.

#### Returns

isalnum returns non-zero if c is a letter (a-z or A-Z) or a digit (0-9).

# Portability

isalnum is ANSI C.

No OS subroutines are required.

# 3.2 isalpha—alphabetic character predicate

# **Synopsis**

```
#include <ctype.h>
int isalpha(int c);
```

# Description

isalpha is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero when c represents an alphabetic ASCII character, and 0 otherwise. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isalpha'.

#### Returns

isalpha returns non-zero if c is a letter (A-Z or a-z).

# Portability

isalpha is ANSI C.

# 3.3 isascii—ASCII character predicate

# **Synopsis**

```
#include <ctype.h>
int isascii(int c);
```

# Description

isascii is a macro which returns non-zero when c is an ASCII character, and 0 otherwise. It is defined for all integer values.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isascii'.

#### Returns

isascii returns non-zero if the low order byte of c is in the range 0 to 127 (0x00-0x7F).

# **Portability**

isascii is ANSI  ${\rm C.}$ 

# 3.4 iscntrl—control character predicate

# **Synopsis**

```
#include <ctype.h>
int iscntrl(int c);
```

## Description

iscntrl is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for control characters, and 0 for other characters. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef iscntrl'.

#### Returns

iscntrl returns non-zero if c is a delete character or ordinary control character (0x7F or 0x00-0x1F).

## **Portability**

iscntrl is ANSI C.

# 3.5 isdigit—decimal digit predicate

# **Synopsis**

```
#include <ctype.h>
int isdigit(int c);
```

# Description

is digit is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for decimal digits, and 0 for other characters. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isdigit'.

#### Returns

isdigit returns non-zero if c is a decimal digit (0-9).

# Portability

isdigit is ANSI C.

# 3.6 islower—lowercase character predicate

# **Synopsis**

```
#include <ctype.h>
int islower(int c);
```

# Description

is lower is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for minuscules (lowercase alphabetic characters), and 0 for other characters. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef islower'.

#### Returns

islower returns non-zero if c is a lowercase letter (a-z).

# Portability

islower is ANSI C.

# 3.7 isprint, isgraph—printable character predicates

# **Synopsis**

```
#include <ctype.h>
int isprint(int c);
int isgraph(int c);
```

## Description

isprint is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for printable characters, and 0 for other character arguments. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining either macro using '#undef isprint' or '#undef isgraph'.

## Returns

isprint returns non-zero if c is a printing character, (0x20-0x7E). isgraph behaves identically to isprint, except that the space character (0x20) is excluded.

# Portability

isprint and isgraph are ANSI C.

# 3.8 ispunct—punctuation character predicate

# **Synopsis**

```
#include <ctype.h>
int ispunct(int c);
```

# Description

ispunct is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for printable punctuation characters, and 0 for other characters. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef ispunct'.

#### Returns

ispunct returns non-zero if c is a printable punctuation character (isgraph(c) && !isalnum(c)).

## **Portability**

ispunct is ANSI C.

# 3.9 isspace—whitespace character predicate

# **Synopsis**

```
#include <ctype.h>
int isspace(int c);
```

# Description

isspace is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for whitespace characters, and 0 for other characters. It is defined only when  ${\tt isascii}(c)$  is true or c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isspace'.

#### Returns

isspace returns non-zero if c is a space, tab, carriage return, new line, vertical tab, or formfeed (0x09-0x0D, 0x20).

## **Portability**

isspace is ANSI C.

# 3.10 isupper—uppercase character predicate

# **Synopsis**

```
#include <ctype.h>
int isupper(int c);
```

# Description

isupper is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for uppercase letters (A-Z), and 0 for other characters. It is defined only when isascii(c) is true or c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isupper'.

#### Returns

isupper returns non-zero if c is a uppercase letter (A-Z).

# Portability

isupper is ANSI C.

# 3.11 isxdigit—hexadecimal digit predicate

# **Synopsis**

```
#include <ctype.h>
int isxdigit(int c);
```

# Description

isxdigit is a macro which classifies ASCII integer values by table lookup. It is a predicate returning non-zero for hexadecimal digits, and 0 for other characters. It is defined only if c is representable as an unsigned char or if c is EOF.

You can use a compiled subroutine instead of the macro definition by undefining the macro using '#undef isxdigit'.

#### Returns

isxdigit returns non-zero if c is a hexadecimal digit (0-9, a-f, or A-F).

# Portability

isxdigit is ANSI C.

# 3.12 toascii—force integers to ASCII range

# **Synopsis**

```
#include <ctype.h>
int toascii(int c);
```

# Description

toascii is a macro which coerces integers to the ASCII range (0–127) by zeroing any higher-order bits.

You can use a compiled subroutine instead of the macro definition by undefining this macro using '#undef toascii'.

#### Returns

toascii returns integers between 0 and 127.

# Portability

toascii is not ANSI C.

# 3.13 tolower—translate characters to lowercase

#### **Synopsis**

```
#include <ctype.h>
int tolower(int c);
int _tolower(int c);
```

#### Description

tolower is a macro which converts uppercase characters to lowercase, leaving all other characters unchanged. It is only defined when c is an integer in the range EOF to 255.

You can use a compiled subroutine instead of the macro definition by undefining this macro using '#undef tolower'.

\_tolower performs the same conversion as tolower, but should only be used when c is known to be an uppercase character (A-Z).

#### Returns

tolower returns the lowercase equivalent of c when it is a character between A and Z, and c otherwise.

\_tolower returns the lowercase equivalent of c when it is a character between A and Z. If c is not one of these characters, the behaviour of \_tolower is undefined.

#### **Portability**

tolower is ANSI C. \_tolower is not recommended for portable programs.

# 3.14 toupper—translate characters to uppercase

# **Synopsis**

```
#include <ctype.h>
int toupper(int c);
int _toupper(int c);
```

#### Description

toupper is a macro which converts lowercase characters to uppercase, leaving all other characters unchanged. It is only defined when c is an integer in the range EOF to 255.

You can use a compiled subroutine instead of the macro definition by undefining this macro using '#undef toupper'.

\_toupper performs the same conversion as toupper, but should only be used when c is known to be a lowercase character (a-z).

#### Returns

toupper returns the uppercase equivalent of c when it is a character between **a** and **z**, and c otherwise.

\_toupper returns the uppercase equivalent of c when it is a character between a and z. If c is not one of these characters, the behaviour of \_toupper is undefined.

## Portability

toupper is ANSI C. \_toupper is not recommended for portable programs.

# 3.15 iswalnum—alphanumeric wide character test

# **Synopsis**

```
#include <wctype.h>
int iswalnum(wint_t c);
```

# Description

iswalnum is a function which classifies wide-character values that are alphanumeric.

#### Returns

iswalnum returns non-zero if c is a alphanumeric wide character.

# Portability

iswalnum is C99.

# 3.16 iswalpha—alphabetic wide character test

# **Synopsis**

```
#include <wctype.h>
int iswalpha(wint_t c);
```

# Description

iswalpha is a function which classifies wide-character values that are alphabetic.

#### Returns

iswalpha returns non-zero if c is an alphabetic wide character.

# Portability

iswalpha is C99.

# 3.17 iswcntrl—control wide character test

# Synopsis

```
#include <wctype.h>
int iswcntrl(wint_t c);
```

# Description

iswcntrl is a function which classifies wide-character values that are categorized as control characters.

#### Returns

iswcntrl returns non-zero if c is a control wide character.

# Portability

iswcntrl is C99.

# 3.18 iswblank—blank wide character test

# **Synopsis**

```
#include <wctype.h>
int iswblank(wint_t c);
```

# Description

iswblank is a function which classifies wide-character values that are categorized as blank.

#### Returns

iswblank returns non-zero if c is a blank wide character.

# Portability

iswblank is C99.

# 3.19 iswdigit—decimal digit wide character test

# **Synopsis**

```
#include <wctype.h>
int iswdigit(wint_t c);
```

# Description

iswdigit is a function which classifies wide-character values that are decimal digits.

#### Returns

iswdigit returns non-zero if c is a decimal digit wide character.

# Portability

iswdigit is C99.

# 3.20 iswgraph—graphic wide character test

# **Synopsis**

```
#include <wctype.h>
int iswgraph(wint_t c);
```

# Description

iswgraph is a function which classifies wide-character values that are graphic.

#### Returns

iswgraph returns non-zero if c is a graphic wide character.

# Portability

iswgraph is C99.

# 3.21 iswlower—lowercase wide character test

# **Synopsis**

```
#include <wctype.h>
int iswlower(wint_t c);
```

# Description

iswlower is a function which classifies wide-character values that have uppercase translations.

#### Returns

iswlower returns non-zero if c is a lowercase wide character.

# Portability

iswlower is C99.

# 3.22 iswprint—printable wide character test

# Synopsis

```
#include <wctype.h>
int iswprint(wint_t c);
```

# Description

iswprint is a function which classifies wide-character values that are printable.

#### Returns

iswprint returns non-zero if c is a printable wide character.

# Portability

iswprint is C99.

# 3.23 iswpunct—punctuation wide character test

# **Synopsis**

```
#include <wctype.h>
int iswpunct(wint_t c);
```

# Description

iswpunct is a function which classifies wide-character values that are punctuation.

#### Returns

iswpunct returns non-zero if c is a punctuation wide character.

# Portability

iswpunct is C99.

# 3.24 iswspace—whitespace wide character test

# Synopsis

```
#include <wctype.h>
int iswspace(wint_t c);
```

# Description

iswspace is a function which classifies wide-character values that are categorized as white-space.

#### Returns

iswspace returns non-zero if c is a whitespace wide character.

# Portability

iswspace is C99.

# 3.25 iswupper—uppercase wide character test

# Synopsis

```
#include <wctype.h>
int iswupper(wint_t c);
```

# Description

is wupper is a function which classifies wide-character values that have upper case translations.

#### Returns

is wupper returns non-zero if c is a uppercase wide character.

# Portability

iswupper is C99.

# 3.26 iswxdigit—hexadecimal digit wide character test

# **Synopsis**

```
#include <wctype.h>
int iswxdigit(wint_t c);
```

# Description

iswxdigit is a function which classifies wide character values that are hexadecimal digits.

#### Returns

iswxdigit returns non-zero if c is a hexadecimal digit wide character.

# Portability

iswxdigit is C99.

# 3.27 iswctype—extensible wide-character test

# **Synopsis**

```
#include <wctype.h>
int iswctype(wint_t c, wctype_t desc);
```

# Description

iswctype is a function which classifies wide-character values using the wide-character test specified by desc.

# Returns

iswctype returns non-zero if and only if c matches the test specified by desc. If desc is unknown, zero is returned.

# Portability

iswctype is C99.

# 3.28 wctype—get wide-character classification type

#### Synopsis

```
#include <wctype.h>
wctype_t wctype(const char *c);
```

#### Description

wctype is a function which takes a string c and gives back the appropriate wctype\_t type value associated with the string, if one exists. The following values are guaranteed to be recognized: "alnum", "alpha", "blank", "cntrl", "digit", "graph", "lower", "print", "punct", "space", "upper", and "xdigit".

#### Returns

wctype returns 0 and sets errno to EINVAL if the given name is invalid. Otherwise, it returns a valid non-zero wctype\_t value.

# **Portability**

wctype is C99.

# 3.29 towlower—translate wide characters to lowercase

# **Synopsis**

```
#include <wctype.h>
wint_t towlower(wint_t c);
```

# Description

towlower is a function which converts uppercase wide characters to lowercase, leaving all other characters unchanged.

#### Returns

towlower returns the lowercase equivalent of c when it is a uppercase wide character; otherwise, it returns the input character.

# Portability

towlower is C99.

# 3.30 towupper—translate wide characters to uppercase

# **Synopsis**

```
#include <wctype.h>
wint_t towupper(wint_t c);
```

# Description

towupper is a function which converts lowercase wide characters to uppercase, leaving all other characters unchanged.

#### Returns

towupper returns the uppercase equivalent of c when it is a lowercase wide character, otherwise, it returns the input character.

# Portability

towupper is C99.

# 3.31 towctrans—extensible wide-character translation

# **Synopsis**

```
#include <wctype.h>
wint_t towctrans(wint_t c, wctrans_t w);
```

# Description

towctrans is a function which converts wide characters based on a specified translation type w. If the translation type is invalid or cannot be applied to the current character, no change to the character is made.

#### Returns

towctrans returns the translated equivalent of c when it is a valid for the given translation, otherwise, it returns the input character. When the translation type is invalid, errno is set EINVAL.

# **Portability**

towctrans is C99.

# 3.32 wctrans—get wide-character translation type

# **Synopsis**

```
#include <wctype.h>
wctrans_t wctrans(const char *c);
```

# Description

wctrans is a function which takes a string c and gives back the appropriate wctrans\_t type value associated with the string, if one exists. The following values are guaranteed to be recognized: "tolower" and "toupper".

#### Returns

wctrans returns 0 and sets errno to EINVAL if the given name is invalid. Otherwise, it returns a valid non-zero wctrans\_t value.

#### **Portability**

wctrans is C99.

# 4 Input and Output ('stdio.h')

This chapter comprises functions to manage files or other input/output streams. Among these functions are subroutines to generate or scan strings according to specifications from a format string.

The underlying facilities for input and output depend on the host system, but these functions provide a uniform interface.

The corresponding declarations are in 'stdio.h'.

The reentrant versions of these functions use macros

```
_stdin_r(reent)
_stdout_r(reent)
_stderr_r(reent)
```

instead of the globals stdin, stdout, and stderr. The argument <[reent]> is a pointer to a reentrancy structure.

# 4.1 clearerr—clear file or stream error indicator

## **Synopsis**

```
#include <stdio.h>
void clearerr(FILE *fp);
```

# Description

The stdio functions maintain an error indicator with each file pointer fp, to record whether any read or write errors have occurred on the associated file or stream. Similarly, it maintains an end-of-file indicator to record whether there is no more data in the file.

Use clearerr to reset both of these indicators.

See ferror and feof to query the two indicators.

#### Returns

clearerr does not return a result.

# **Portability**

ANSI C requires clearerr.

# 4.2 diprintf, vdiprintf—print to a file descriptor (integer only)

# Synopsis

# Description

diprintf and vdiprintf are similar to dprintf and vdprintf, except that only integer format specifiers are processed.

The functions \_diprintf\_r and \_vdiprintf\_r are simply reentrant versions of the functions above.

#### Returns

Similar to dprintf and vdprintf.

#### **Portability**

This set of functions is an integer-only extension, and is not portable.

Supporting OS subroutines required: sbrk, write.

# 4.3 dprintf, vdprintf—print to a file descriptor

# Synopsis

# Description

dprintf and vdprintf allow printing a format, similarly to printf, but write to a file descriptor instead of to a FILE stream.

The functions \_dprintf\_r and \_vdprintf\_r are simply reentrant versions of the functions above.

#### Returns

The return value and errors are exactly as for write, except that errno may also be set to ENOMEM if the heap is exhausted.

#### Portability

This function is originally a GNU extension in glibc and is not portable.

Supporting OS subroutines required: sbrk, write.

# 4.4 fclose—close a file

# **Synopsis**

```
#include <stdio.h>
int fclose(FILE *fp);
int _fclose_r(struct _reent *reent, FILE *fp);
```

# Description

If the file or stream identified by fp is open, fclose closes it, after first ensuring that any pending data is written (by calling fflush(fp)).

The alternate function \_fclose\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

fclose returns 0 if successful (including when fp is NULL or not an open file); otherwise, it returns EOF.

#### **Portability**

fclose is required by ANSI C.

Required OS subroutines: close, fstat, isatty, lseek, read, sbrk, write.

# 4.5 fcloseall—close all files

# **Synopsis**

```
#include <stdio.h>
int fcloseall(void);
int _fcloseall_r (struct _reent *ptr);
```

# Description

fcloseall closes all files in the current reentrancy struct's domain. The function  $_{\tt fcloseall\_r}$  is the same function, except the reentrancy struct is passed in as the ptr argument.

This function is not recommended as it closes all streams, including the std streams.

#### Returns

fclose returns 0 if all closes are successful. Otherwise, EOF is returned.

# Portability

fcloseall is a glibc extension.

Required OS subroutines: close, fstat, isatty, lseek, read, sbrk, write.

# 4.6 fdopen—turn open file into a stream

# **Synopsis**

# Description

fdopen produces a file descriptor of type FILE \*, from a descriptor for an already-open file (returned, for example, by the system subroutine open rather than by fopen). The *mode* argument has the same meanings as in fopen.

#### Returns

File pointer or NULL, as for fopen.

# **Portability**

fdopen is ANSI.

# 4.7 feof—test for end of file

# **Synopsis**

```
#include <stdio.h>
int feof(FILE *fp);
```

# Description

feof tests whether or not the end of the file identified by fp has been reached.

#### Returns

feof returns 0 if the end of file has not yet been reached; if at end of file, the result is nonzero.

# Portability

feof is required by ANSI C.

# 4.8 ferror—test whether read/write error has occurred

# **Synopsis**

```
#include <stdio.h>
int ferror(FILE *fp);
```

# Description

The stdio functions maintain an error indicator with each file pointer fp, to record whether any read or write errors have occurred on the associated file or stream. Use ferror to query this indicator.

See clearerr to reset the error indicator.

#### Returns

ferror returns 0 if no errors have occurred; it returns a nonzero value otherwise.

# Portability

ANSI C requires ferror.

# 4.9 fflush—flush buffered file output

#### **Synopsis**

```
#include <stdio.h>
int fflush(FILE *fp);
int _fflush_r(struct _reent *reent, FILE *fp);
```

#### Description

The stdio output functions can buffer output before delivering it to the host system, in order to minimize the overhead of system calls.

Use fflush to deliver any such pending output (for the file or stream identified by fp) to the host system.

If fp is NULL, fflush delivers pending output from all open files.

Additionally, if fp is a seekable input stream visiting a file descriptor, set the position of the file descriptor to match next unread byte, useful for obeying POSIX semantics when ending a process without consuming all input from the stream.

The alternate function \_fflush\_r is a reentrant version, where the extra argument reent is a pointer to a reentrancy structure, and fp must not be NULL.

#### Returns

fflush returns 0 unless it encounters a write error; in that situation, it returns EOF.

#### Portability

ANSI C requires fflush. The behavior on input streams is only specified by POSIX, and not all implementations follow POSIX rules.

# 4.10 fgetc—get a character from a file or stream

# **Synopsis**

```
#include <stdio.h>
int fgetc(FILE *fp);

#include <stdio.h>
int _fgetc_r(struct _reent *ptr, FILE *fp);
```

#### Description

Use fgetc to get the next single character from the file or stream identified by fp. As a side effect, fgetc advances the file's current position indicator.

For a macro version of this function, see getc.

The function \_fgetc\_r is simply a reentrant version of fgetc that is passed the additional reentrant structure pointer argument: ptr.

#### Returns

The next character (read as an unsigned char, and cast to int), unless there is no more data, or the host system reports a read error; in either of these situations, fgetc returns EOF.

You can distinguish the two situations that cause an EOF result by using the ferror and feof functions.

#### **Portability**

ANSI C requires fgetc.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 4.11 fgetpos—record position in a stream or file

#### **Synopsis**

```
#include <stdio.h>
int fgetpos(FILE *fp, fpos_t *pos);
int _fgetpos_r(struct _reent *ptr, FILE *fp, fpos_t *pos);
```

#### Description

Objects of type FILE can have a "position" that records how much of the file your program has already read. Many of the stdio functions depend on this position, and many change it as a side effect.

You can use fgetpos to report on the current position for a file identified by fp; fgetpos will write a value representing that position at \*pos. Later, you can use this value with fsetpos to return the file to this position.

In the current implementation, fgetpos simply uses a character count to represent the file position; this is the same number that would be returned by ftell.

#### Returns

fgetpos returns 0 when successful. If fgetpos fails, the result is 1. Failure occurs on streams that do not support positioning; the global errno indicates this condition with the value ESPIPE.

#### **Portability**

fgetpos is required by the ANSI C standard, but the meaning of the value it records is not specified beyond requiring that it be acceptable as an argument to fsetpos. In particular, other conforming C implementations may return a different result from ftell than what fgetpos writes at \*pos.

# 4.12 fgets—get character string from a file or stream

## **Synopsis**

```
#include <stdio.h>
char *fgets(char *buf, int n, FILE *fp);

#include <stdio.h>
char *_fgets_r(struct _reent *ptr, char *buf, int n, FILE *fp);
```

## Description

Reads at most n-1 characters from fp until a newline is found. The characters including to the newline are stored in buf. The buffer is terminated with a 0.

The  $\_fgets\_r$  function is simply the reentrant version of fgets and is passed an additional reentrancy structure pointer: ptr.

#### Returns

fgets returns the buffer passed to it, with the data filled in. If end of file occurs with some data already accumulated, the data is returned with no other indication. If no data are read, NULL is returned instead.

#### Portability

fgets should replace all uses of gets. Note however that fgets returns all of the data, while gets removes the trailing newline (with no indication that it has done so.)

# 4.13 fgetwc, getwc—get a wide character from a file or stream

## **Synopsis**

```
#include <stdio.h>
#include <wchar.h>
wint_t fgetwc(FILE *fp);

#include <stdio.h>
#include <wchar.h>
wint_t _fgetwc_r(struct _reent *ptr, FILE *fp);

#include <stdio.h>
#include <wchar.h>
wint_t getwc(FILE *fp);

#include <stdio.h>
#include <stdio.h>
#include <stdio.h>
#include <stdio.h>
wint_t getwc(FILE *fp);
```

#### Description

Use fgetwc to get the next wide character from the file or stream identified by fp. As a side effect, fgetwc advances the file's current position indicator.

The getwc function or macro functions identically to fgetwc. It may be implemented as a macro, and may evaluate its argument more than once. There is no reason ever to use it.

\_fgetwc\_r and \_getwc\_r are simply reentrant versions of fgetwc and getwc that are passed the additional reentrant structure pointer argument: ptr.

### Returns

The next wide character cast to wint\_t), unless there is no more data, or the host system reports a read error; in either of these situations, fgetwc and getwc return WEOF.

You can distinguish the two situations that cause an EOF result by using the ferror and feof functions.

#### **Portability**

C99, POSIX.1-2001

# 4.14 fgetws—get wide character string from a file or stream Synopsis

```
#include <wchar.h>
wchar_t *fgetws(wchar_t *ws, int n, FILE *fp);

#include <wchar.h>
wchar_t *_fgetws_r(struct _reent *ptr, wchar_t *ws, int n, FILE *fp);
```

#### Description

Reads at most n-1 wide characters from fp until a newline is found. The wide characters including to the newline are stored in ws. The buffer is terminated with a 0.

The \_fgetws\_r function is simply the reentrant version of fgetws and is passed an additional reentrancy structure pointer: ptr.

#### Returns

fgetws returns the buffer passed to it, with the data filled in. If end of file occurs with some data already accumulated, the data is returned with no other indication. If no data are read, NULL is returned instead.

### Portability

C99, POSIX.1-2001

# 4.15 fileno—return file descriptor associated with stream

# **Synopsis**

```
#include <stdio.h>
int fileno(FILE *fp);
```

### Description

You can use fileno to return the file descriptor identified by fp.

#### Returns

fileno returns a non-negative integer when successful. If fp is not an open stream, fileno returns -1.

## Portability

fileno is not part of ANSI C. POSIX requires fileno.

Supporting OS subroutines required: none.

# 4.16 fmemopen—open a stream around a fixed-length string

FILE \*fmemopen(void \*restrict buf, size\_t size,

const char \*restrict mode);

Synopsis

#include <stdio.h>

## Description

fmemopen creates a seekable FILE stream that wraps a fixed-length buffer of size bytes starting at buf. The stream is opened with mode treated as in fopen, where append mode starts writing at the first NUL byte. If buf is NULL, then size bytes are automatically provided as if by malloc, with the initial size of 0, and mode must contain + so that data can be read after it is written.

The stream maintains a current position, which moves according to bytes read or written, and which can be one past the end of the array. The stream also maintains a current file size, which is never greater than size. If mode starts with r, the position starts at 0, and file size starts at size if buf was provided. If mode starts with w, the position and file size start at 0, and if buf was provided, the first byte is set to NUL. If mode starts with a, the position and file size start at the location of the first NUL byte, or else size if buf was provided.

When reading, NUL bytes have no significance, and reads cannot exceed the current file size. When writing, the file size can increase up to size as needed, and NUL bytes may be embedded in the stream (see open\_memstream for an alternative that automatically enlarges the buffer). When the stream is flushed or closed after a write that changed the file size, a NUL byte is written at the current position if there is still room; if the stream is not also open for reading, a NUL byte is additionally written at the last byte of buf when the stream has exceeded size, so that a write-only buf is always NUL-terminated when the stream is flushed or closed (and the initial size should take this into account). It is not possible to seek outside the bounds of size. A NUL byte written during a flush is restored to its previous value when seeking elsewhere in the string.

#### Returns

The return value is an open FILE pointer on success. On error, NULL is returned, and errno will be set to EINVAL if size is zero or mode is invalid, ENOMEM if buf was NULL and memory could not be allocated, or EMFILE if too many streams are already open.

#### **Portability**

This function is being added to POSIX 200x, but is not in POSIX 2001.

Supporting OS subroutines required: sbrk.

# 4.17 fopen—open a file

#### **Synopsis**

#### Description

fopen initializes the data structures needed to read or write a file. Specify the file's name as the string at file, and the kind of access you need to the file with the string at mode.

The alternate function \_fopen\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

Three fundamental kinds of access are available: read, write, and append. \*mode must begin with one of the three characters 'r', 'w', or 'a', to select one of these:

- r Open the file for reading; the operation will fail if the file does not exist, or if the host system does not permit you to read it.
- W Open the file for writing from the beginning of the file: effectively, this always creates a new file. If the file whose name you specified already existed, its old contents are discarded.
- a Open the file for appending data, that is writing from the end of file. When you open a file this way, all data always goes to the current end of file; you cannot change this using fseek.

Some host systems distinguish between "binary" and "text" files. Such systems may perform data transformations on data written to, or read from, files opened as "text". If your system is one of these, then you can append a 'b' to any of the three modes above, to specify that you are opening the file as a binary file (the default is to open the file as a text file).

'rb', then, means "read binary"; 'wb', "write binary"; and 'ab', "append binary".

To make C programs more portable, the 'b' is accepted on all systems, whether or not it makes a difference.

Finally, you might need to both read and write from the same file. You can also append a '+' to any of the three modes, to permit this. (If you want to append both 'b' and '+', you can do it in either order: for example, "rb+" means the same thing as "r+b" when used as a mode string.)

Use "r+" (or "rb+") to permit reading and writing anywhere in an existing file, without discarding any data; "w+" (or "wb+") to create a new file (or begin by discarding all data from an old one) that permits reading and writing anywhere in it; and "a+" (or "ab+") to permit reading anywhere in an existing file, but writing only at the end.

#### Returns

fopen returns a file pointer which you can use for other file operations, unless the file you requested could not be opened; in that situation, the result is NULL. If the reason for failure was an invalid string at *mode*, errno is set to EINVAL.

# Portability

fopen is required by ANSI C.

# 4.18 fopencookie—open a stream with custom callbacks

#### **Synopsis**

#### Description

fopencookie creates a FILE stream where I/O is performed using custom callbacks. The callbacks are registered via the structure:

typedef ssize\_t (\*cookie\_read\_function\_t)(void \*\_cookie, char \*\_buf, size\_t \_n); typedef ssize\_t (\*cookie\_write\_function\_t)(void \*\_cookie, const char \*\_buf, size\_t \_n); typedef int (\*cookie\_seek\_function\_t)(void \*\_cookie, off\_t \*\_off, int \_whence); typedef int (\*cookie\_close\_function\_t)(void \*\_cookie);

```
typedef struct
{
cookie_read_function_t *read;
cookie_write_function_t *write;
cookie_seek_function_t *seek;
cookie_close_function_t *close;
} cookie_io_functions_t;
```

The stream is opened with mode treated as in fopen. The callbacks functions.read and functions.write may only be NULL when mode does not require them.

functions.read should return -1 on failure, or else the number of bytes read (0 on EOF). It is similar to read, except that cookie will be passed as the first argument.

functions.write should return -1 on failure, or else the number of bytes written. It is similar to write, except that cookie will be passed as the first argument.

functions.seek should return -1 on failure, and 0 on success, with \_off set to the current file position. It is a cross between lseek and fseek, with the \_whence argument interpreted in the same manner. A NULL functions.seek makes the stream behave similarly to a pipe in relation to stdio functions that require positioning.

functions.close should return -1 on failure, or 0 on success. It is similar to close, except that cookie will be passed as the first argument. A NULL functions.close merely flushes all data then lets fclose succeed. A failed close will still invalidate the stream.

Read and write I/O functions are allowed to change the underlying buffer on fully buffered or line buffered streams by calling setvbuf. They are also not required to completely fill or empty the buffer. They are not, however, allowed to change streams from unbuffered to buffered or to change the state of the line buffering flag. They must also be prepared to have read or write calls occur on buffers other than the one most recently specified.

#### Returns

The return value is an open FILE pointer on success. On error, NULL is returned, and errno will be set to EINVAL if a function pointer is missing or *mode* is invalid, ENOMEM if the stream cannot be created, or EMFILE if too many streams are already open.

#### **Portability**

This function is a newlib extension, copying the prototype from Linux. It is not portable. See also the funopen interface from BSD.

Supporting OS subroutines required: sbrk.

# 4.19 fpurge—discard pending file I/O

## **Synopsis**

```
#include <stdio.h>
int fpurge(FILE *fp);

int _fpurge_r(struct _reent *reent, FILE *fp);

#include <stdio.h>
#include <stdio_ext.h>
void __fpurge(FILE *fp);
```

## Description

Use fpurge to clear all buffers of the given stream. For output streams, this discards data not yet written to disk. For input streams, this discards any data from ungetc and any data retrieved from disk but not yet read via getc. This is more severe than fflush, and generally is only needed when manually altering the underlying file descriptor of a stream.

\_\_fpurge behaves exactly like fpurge but does not return a value.

The alternate function \_fpurge\_r is a reentrant version, where the extra argument reent is a pointer to a reentrancy structure, and fp must not be NULL.

#### Returns

fpurge returns 0 unless fp is not valid, in which case it returns EOF and sets errno.

#### **Portability**

These functions are not portable to any standard.

No supporting OS subroutines are required.

# 4.20 fputc—write a character on a stream or file

## **Synopsis**

```
#include <stdio.h>
int fputc(int ch, FILE *fp);

#include <stdio.h>
int _fputc_r(struct _rent *ptr, int ch, FILE *fp);
```

#### Description

fputc converts the argument *ch* from an int to an unsigned char, then writes it to the file or stream identified by *fp*.

If the file was opened with append mode (or if the stream cannot support positioning), then the new character goes at the end of the file or stream. Otherwise, the new character is written at the current value of the position indicator, and the position indicator oadvances by one.

For a macro version of this function, see putc.

The \_fputc\_r function is simply a reentrant version of fputc that takes an additional reentrant structure argument: ptr.

#### Returns

If successful, fputc returns its argument ch. If an error intervenes, the result is EOF. You can use 'ferror(fp)' to query for errors.

#### **Portability**

fputc is required by ANSI C.

# 4.21 fputs—write a character string in a file or stream

## **Synopsis**

```
#include <stdio.h>
int fputs(const char *s, FILE *fp);

#include <stdio.h>
int _fputs_r(struct _reent *ptr, const char *s, FILE *fp);
```

#### Description

fputs writes the string at s (but without the trailing null) to the file or stream identified by fp.

\_fputs\_r is simply the reentrant version of fputs that takes an additional reentrant struct pointer argument: ptr.

#### Returns

If successful, the result is 0; otherwise, the result is EOF.

#### **Portability**

ANSI C requires fputs, but does not specify that the result on success must be 0; any non-negative value is permitted.

# 4.22 fputwc, putwc—write a wide character on a stream or file

## **Synopsis**

```
#include <stdio.h>
#include <wchar.h>
wint_t fputwc(wchar_t wc, FILE *fp);

#include <stdio.h>
#include <wchar.h>
wint_t _fputwc_r(struct _reent *ptr, wchar_t wc, FILE *fp);

#include <stdio.h>
#include <wchar.h>
wint_t putwc(wchar_t wc, FILE *fp);

#include <stdio.h>
#include <stdio.h
#
```

#### Description

fputwc writes the wide character argument wc to the file or stream identified by fp.

If the file was opened with append mode (or if the stream cannot support positioning), then the new wide character goes at the end of the file or stream. Otherwise, the new wide character is written at the current value of the position indicator, and the position indicator oadvances by one.

The putwc function or macro functions identically to fputwc. It may be implemented as a macro, and may evaluate its argument more than once. There is no reason ever to use it.

The \_fputwc\_r and \_putwc\_r functions are simply reentrant versions of fputwc and putwc that take an additional reentrant structure argument: ptr.

#### Returns

If successful, fputwc and putwc return their argument wc. If an error intervenes, the result is EOF. You can use 'ferror(fp)' to query for errors.

#### **Portability**

C99, POSIX.1-2001

# 4.23 fputws—write a wide character string in a file or stream

# Synopsis

```
#include <wchar.h>
int fputws(const wchar_t *ws, FILE *fp);

#include <wchar.h>
int _fputws_r(struct _reent *ptr, const wchar_t *ws, FILE *fp);
```

#### Description

fputws writes the wide character string at ws (but without the trailing null) to the file or stream identified by fp.

\_fputws\_r is simply the reentrant version of fputws that takes an additional reentrant struct pointer argument: ptr.

#### Returns

If successful, the result is a non-negative integer; otherwise, the result is -1 to indicate an error.

### Portability

C99, POSIX.1-2001

# 4.24 fread—read array elements from a file

#### **Synopsis**

```
#include <stdio.h>
size_t fread(void *buf, size_t size, size_t count,
    FILE *fp);

#include <stdio.h>
size_t _fread_r(struct _reent *ptr, void *buf,
    size_t size, size_t count, FILE *fp);
```

### Description

fread attempts to copy, from the file or stream identified by fp, count elements (each of size size) into memory, starting at buf. fread may copy fewer elements than count if an error, or end of file, intervenes.

 ${\tt fread}$  also advances the file position indicator (if any) for fp by the number of characters actually read.

 $_{\tt fread\_r}$  is simply the reentrant version of  $_{\tt fread}$  that takes an additional reentrant structure pointer argument: ptr.

#### Returns

The result of **fread** is the number of elements it succeeded in reading.

#### **Portability**

ANSI C requires fread.

# 4.25 freopen—open a file using an existing file descriptor

## **Synopsis**

```
#include <stdio.h>
FILE *freopen(const char *file, const char *mode,
    FILE *fp);
FILE *_freopen_r(struct _reent *ptr, const char *file,
    const char *mode, FILE *fp);
```

#### Description

Use this variant of fopen if you wish to specify a particular file descriptor fp (notably stdin, stdout, or stderr) for the file.

If fp was associated with another file or stream, freopen closes that other file or stream (but ignores any errors while closing it).

file and mode are used just as in fopen.

If file is NULL, the underlying stream is modified rather than closed. The file cannot be given a more permissive access mode (for example, a *mode* of "w" will fail on a read-only file descriptor), but can change status such as append or binary mode. If modification is not possible, failure occurs.

#### Returns

If successful, the result is the same as the argument fp. If the file cannot be opened as specified, the result is NULL.

#### **Portability**

ANSI C requires freopen.

# 4.26 fseek, fseeko—set file position

## **Synopsis**

#### Description

Objects of type FILE can have a "position" that records how much of the file your program has already read. Many of the stdio functions depend on this position, and many change it as a side effect.

You can use fseek/fseeko to set the position for the file identified by fp. The value of offset determines the new position, in one of three ways selected by the value of whence (defined as macros in 'stdio.h'):

SEEK\_SET—offset is the absolute file position (an offset from the beginning of the file) desired. offset must be positive.

SEEK\_CUR—offset is relative to the current file position. offset can meaningfully be either positive or negative.

SEEK\_END—offset is relative to the current end of file. offset can meaningfully be either positive (to increase the size of the file) or negative.

See ftell/ftello to determine the current file position.

#### Returns

fseek/fseeko return 0 when successful. On failure, the result is EOF. The reason for failure is indicated in errno: either ESPIPE (the stream identified by fp doesn't support repositioning) or EINVAL (invalid file position).

#### **Portability**

ANSI C requires fseek.

fseeko is defined by the Single Unix specification.

# 4.27 fsetpos—restore position of a stream or file

## **Synopsis**

## Description

Objects of type FILE can have a "position" that records how much of the file your program has already read. Many of the stdio functions depend on this position, and many change it as a side effect.

You can use fsetpos to return the file identified by fp to a previous position \*pos (after first recording it with fgetpos).

See fseek for a similar facility.

#### Returns

fgetpos returns 0 when successful. If fgetpos fails, the result is 1. The reason for failure is indicated in errno: either ESPIPE (the stream identified by fp doesn't support repositioning) or EINVAL (invalid file position).

#### **Portability**

ANSI C requires fsetpos, but does not specify the nature of \*pos beyond identifying it as written by fgetpos.

# 4.28 ftell, ftello—return position in a stream or file

#### **Synopsis**

```
#include <stdio.h>
long ftell(FILE *fp);
off_t ftello(FILE *fp);
long _ftell_r(struct _reent *ptr, FILE *fp);
off_t _ftello_r(struct _reent *ptr, FILE *fp);
```

#### Description

Objects of type FILE can have a "position" that records how much of the file your program has already read. Many of the stdio functions depend on this position, and many change it as a side effect.

The result of ftell/ftello is the current position for a file identified by fp. If you record this result, you can later use it with fseek/fseeko to return the file to this position. The difference between ftell and ftello is that ftell returns long and ftello returns off\_t.

In the current implementation, ftell/ftello simply uses a character count to represent the file position; this is the same number that would be recorded by fgetpos.

#### Returns

ftell/ftello return the file position, if possible. If they cannot do this, they return -1L. Failure occurs on streams that do not support positioning; the global errno indicates this condition with the value ESPIPE.

#### **Portability**

ftell is required by the ANSI C standard, but the meaning of its result (when successful) is not specified beyond requiring that it be acceptable as an argument to fseek. In particular, other conforming C implementations may return a different result from ftell than what fgetpos records.

ftello is defined by the Single Unix specification.

No supporting OS subroutines are required.

# 4.29 funopen, fropen, fwopen—open a stream with custom callbacks

## **Synopsis**

```
#include <stdio.h>
FILE *funopen(const void *cookie,
    int (*readfn) (void *cookie, char *buf, int n),
    int (*writefn) (void *cookie, const char *buf, int n),
    fpos_t (*seekfn) (void *cookie, fpos_t off, int whence),
    int (*closefn) (void *cookie));
FILE *fropen(const void *cookie,
    int (*readfn) (void *cookie, char *buf, int n));
FILE *fwopen(const void *cookie,
    int (*writefn) (void *cookie, const char *buf, int n));
```

#### Description

funopen creates a FILE stream where I/O is performed using custom callbacks. At least one of *readfn* and *writefn* must be provided, which determines whether the stream behaves with mode <"r">>, <"w">>, or <"r+">>.

readfn should return -1 on failure, or else the number of bytes read (0 on EOF). It is similar to read, except that <int> rather than <size\_t> bounds a transaction size, and cookie will be passed as the first argument. A NULL readfn makes attempts to read the stream fail.

writefn should return -1 on failure, or else the number of bytes written. It is similar to write, except that <int> rather than <size\_t> bounds a transaction size, and cookie will be passed as the first argument. A NULL writefn makes attempts to write the stream fail.

seekfn should return (fpos\_t)-1 on failure, or else the current file position. It is similar to lseek, except that cookie will be passed as the first argument. A NULL seekfn makes the stream behave similarly to a pipe in relation to stdio functions that require positioning. This implementation assumes fpos\_t and off\_t are the same type.

closefn should return -1 on failure, or 0 on success. It is similar to close, except that cookie will be passed as the first argument. A NULL closefn merely flushes all data then lets fclose succeed. A failed close will still invalidate the stream.

Read and write I/O functions are allowed to change the underlying buffer on fully buffered or line buffered streams by calling setvbuf. They are also not required to completely fill or empty the buffer. They are not, however, allowed to change streams from unbuffered to buffered or to change the state of the line buffering flag. They must also be prepared to have read or write calls occur on buffers other than the one most recently specified.

The functions fropen and fwopen are convenience macros around funopen that only use the specified callback.

#### Returns

The return value is an open FILE pointer on success. On error, NULL is returned, and errno will be set to EINVAL if a function pointer is missing, ENOMEM if the stream cannot be created, or EMFILE if too many streams are already open.

#### **Portability**

This function is a newlib extension, copying the prototype from BSD. It is not portable. See also the fopencookie interface from Linux.

Supporting OS subroutines required: sbrk.

# 4.30 fwide—set and determine the orientation of a FILE stream

## **Synopsis**

```
#include <wchar.h>
int fwide(FILE *fp, int mode)
int _fwide_r(struct _reent *ptr, FILE *fp, int mode)
```

#### Description

When mode is zero, the fwide function determines the current orientation of fp. It returns a value > 0 if fp is wide-character oriented, i.e. if wide character I/O is permitted but char I/O is disallowed. It returns a value < 0 if fp is byte oriented, i.e. if char I/O is permitted but wide character I/O is disallowed. It returns zero if fp has no orientation yet; in this case the next I/O operation might change the orientation (to byte oriented if it is a char I/O operation, or to wide-character oriented if it is a wide character I/O operation).

Once a stream has an orientation, it cannot be changed and persists until the stream is closed, unless the stream is re-opened with freopen, which removes the orientation of the stream.

When mode is non-zero, the fwide function first attempts to set fp's orientation (to wide-character oriented if mode > 0, or to byte oriented if mode < 0). It then returns a value denoting the current orientation, as above.

### Returns

The fwide function returns fp's orientation, after possibly changing it. A return value > 0 means wide-character oriented. A return value < 0 means byte oriented. A return value of zero means undecided.

#### **Portability**

C99, POSIX.1-2001.

# 4.31 fwrite—write array elements

#### **Synopsis**

#### Description

fwrite attempts to copy, starting from the memory location buf, count elements (each of size size) into the file or stream identified by fp. fwrite may copy fewer elements than count if an error intervenes.

fwrite also advances the file position indicator (if any) for fp by the number of characters actually written.

 $_{\text{fwrite}\_r}$  is simply the reentrant version of fwrite that takes an additional reentrant structure argument: ptr.

#### Returns

If fwrite succeeds in writing all the elements you specify, the result is the same as the argument *count*. In any event, the result is the number of complete elements that fwrite copied to the file.

#### **Portability**

ANSI C requires fwrite.

# 4.32 getc—read a character (macro)

## **Synopsis**

```
#include <stdio.h>
int getc(FILE *fp);

#include <stdio.h>
int _getc_r(struct _reent *ptr, FILE *fp);
```

#### Description

getc is a macro, defined in stdio.h. You can use getc to get the next single character from the file or stream identified by fp. As a side effect, getc advances the file's current position indicator.

For a subroutine version of this macro, see fgetc.

The \_getc\_r function is simply the reentrant version of getc which passes an additional reentrancy structure pointer argument: ptr.

#### Returns

The next character (read as an unsigned char, and cast to int), unless there is no more data, or the host system reports a read error; in either of these situations, getc returns EOF.

You can distinguish the two situations that cause an EOF result by using the ferror and feof functions.

### Portability

ANSI C requires getc; it suggests, but does not require, that getc be implemented as a macro. The standard explicitly permits macro implementations of getc to use the argument more than once; therefore, in a portable program, you should not use an expression with side effects as the getc argument.

# 4.33 getc\_unlocked—non-thread-safe version of getc (macro)

## **Synopsis**

```
#include <stdio.h>
int getc_unlocked(FILE *fp);

#include <stdio.h>
int _getc_unlocked_r(FILE *fp);
```

#### Description

getc\_unlocked is a non-thread-safe version of getc declared in stdio.h. getc\_unlocked may only safely be used within a scope protected by flockfile() (or ftrylockfile()) and funlockfile(). These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE \*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions. If threads are disabled, then getc\_unlocked is equivalent to getc.

The \_getc\_unlocked\_r function is simply the reentrant version of get\_unlocked which passes an additional reentrancy structure pointer argument: ptr.

#### Returns

See getc.

#### **Portability**

POSIX 1003.1 requires getc\_unlocked. getc\_unlocked may be implemented as a macro, so arguments should not have side-effects.

# 4.34 getchar—read a character (macro)

#### **Synopsis**

```
#include <stdio.h>
int getchar(void);
int _getchar_r(struct _reent *reent);
```

## Description

getchar is a macro, defined in stdio.h. You can use getchar to get the next single character from the standard input stream. As a side effect, getchar advances the standard input's current position indicator.

The alternate function \_getchar\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The next character (read as an unsigned char, and cast to int), unless there is no more data, or the host system reports a read error; in either of these situations, getchar returns EOF.

You can distinguish the two situations that cause an EOF result by using 'ferror(stdin)' and 'feof(stdin)'.

#### **Portability**

ANSI C requires getchar; it suggests, but does not require, that getchar be implemented as a macro.

# 4.35 getchar\_unlocked—non-thread-safe version of getchar (macro)

# Synopsis

```
#include <stdio.h>
int getchar_unlocked();

#include <stdio.h>
int _getchar_unlocked_r(struct _reent *ptr);
```

#### Description

getchar\_unlocked is a non-thread-safe version of getchar declared in stdio.h. getchar\_unlocked may only safely be used within a scope protected by flockfile() (or ftrylockfile()) and funlockfile(). These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE \*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions. If threads are disabled, then getchar\_unlocked is equivalent to getchar.

The \_getchar\_unlocked\_r function is simply the reentrant version of getchar\_unlocked which passes an additional reentrancy structure pointer argument: ptr.

#### Returns

See getchar.

#### **Portability**

POSIX 1003.1 requires getchar\_unlocked. getchar\_unlocked may be implemented as a macro.

# 4.36 getdelim—read a line up to a specified line delimiter

## **Synopsis**

```
#include <stdio.h>
int getdelim(char **bufptr, size_t *n,
    int delim, FILE *fp);
```

#### Description

getdelim reads a file fp up to and possibly including a specified delimiter delim. The line is read into a buffer pointed to by bufptr and designated with size \*n. If the buffer is not large enough, it will be dynamically grown by getdelim. As the buffer is grown, the pointer to the size n will be updated.

#### Returns

getdelim returns -1 if no characters were successfully read; otherwise, it returns the number of bytes successfully read. At end of file, the result is nonzero.

#### **Portability**

getdelim is a glibc extension.

No supporting OS subroutines are directly required.

# 4.37 getline—read a line from a file

## **Synopsis**

```
#include <stdio.h>
ssize_t getline(char **bufptr, size_t *n, FILE *fp);
```

#### Description

getline reads a file fp up to and possibly including the newline character. The line is read into a buffer pointed to by bufptr and designated with size \*n. If the buffer is not large enough, it will be dynamically grown by getdelim. As the buffer is grown, the pointer to the size n will be updated.

getline is equivalent to getdelim(bufptr, n, '\n', fp);

#### Returns

getline returns -1 if no characters were successfully read, otherwise, it returns the number of bytes successfully read. at end of file, the result is nonzero.

#### **Portability**

getline is a glibc extension.

No supporting OS subroutines are directly required.

# 4.38 gets—get character string (obsolete, use fgets instead) Synopsis

```
#include <stdio.h>
char *gets(char *buf);
char *_gets_r(struct _reent *reent, char *buf);
```

#### Description

Reads characters from standard input until a newline is found. The characters up to the newline are stored in *buf*. The newline is discarded, and the buffer is terminated with a 0.

This is a *dangerous* function, as it has no way of checking the amount of space available in *buf*. One of the attacks used by the Internet Worm of 1988 used this to overrun a buffer allocated on the stack of the finger daemon and overwrite the return address, causing the daemon to execute code downloaded into it over the connection.

The alternate function <code>\_gets\_r</code> is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

gets returns the buffer passed to it, with the data filled in. If end of file occurs with some data already accumulated, the data is returned with no other indication. If end of file occurs with no data in the buffer, NULL is returned.

# 4.39 getw—read a word (int)

#### **Synopsis**

```
#include <stdio.h>
int getw(FILE *fp);
```

#### Description

getw is a function, defined in stdio.h. You can use getw to get the next word from the file or stream identified by fp. As a side effect, getw advances the file's current position indicator.

#### Returns

The next word (read as an int), unless there is no more data or the host system reports a read error; in either of these situations, getw returns EOF. Since EOF is a valid int, you must use ferror or feof to distinguish these situations.

#### Portability

getw is a remnant of K&R C; it is not part of any ISO C Standard. fread should be used instead. In fact, this implementation of getw is based upon fread.

Supporting OS subroutines required: fread.

# 4.40 getwchar—read a wide character from standard input

## Synopsis

```
#include <wchar.h>
wint_t getwchar(void);
wint_t _getwchar_r(struct _reent *reent);
```

## Description

getwchar function or macro is the wide character equivalent of the getchar function. You can use getwchar to get the next wide character from the standard input stream. As a side effect, getwchar advances the standard input's current position indicator.

The alternate function \_getwchar\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The next wide character cast to wint\_t, unless there is no more data, or the host system reports a read error; in either of these situations, getwchar returns WEOF.

You can distinguish the two situations that cause an WEOF result by using 'ferror(stdin)' and 'feof(stdin)'.

## Portability

C99

# 4.41 mktemp, mkstemp, mkstemps, mkstemps, Synopsis

```
#include <stdlib.h>
char *mktemp(char *path);
char *mkdtemp(char *path);
int mkstemp(char *path);
int mkstemps(char *path, int suffixlen);
int mkostemp(char *path, int flags);
int mkostemps(char *path, int suffixlen, int flags);

char *_mktemp_r(struct _reent *reent, char *path);
char *_mkdtemp_r(struct _reent *reent, char *path);
int *_mkstemp_r(struct _reent *reent, char *path);
int *_mkstemp_r(struct _reent *reent, char *path);
int *_mkstemp_r(struct _reent *reent, char *path, int len);
int *_mkostemp_r(struct _reent *reent, char *path, int flags);
int *_mkostemps_r(struct _reent *reent, char *path, int len, int flags);
```

#### Description

mktemp, mkstemp, and mkstemps attempt to generate a file name that is not yet in use for any existing file. mkstemp and mkstemps create the file and open it for reading and writing; mktemp simply generates the file name (making mktemp a security risk). mkostemp and mkostemps allow the addition of other open flags, such as O\_CLOEXEC, O\_APPEND, or O\_SYNC. On platforms with a separate text mode, mkstemp forces O\_BINARY, while mkostemp allows the choice between O\_BINARY, O\_TEXT, or O for default. mkdtemp attempts to create a directory instead of a file, with a permissions mask of 0700.

You supply a simple pattern for the generated file name, as the string at *path*. The pattern should be a valid filename (including path information if you wish) ending with at least six 'X' characters. The generated filename will match the leading part of the name you supply, with the trailing 'X' characters replaced by some combination of digits and letters. With mkstemps, the 'X' characters end suffixlen bytes before the end of the string.

The alternate functions \_mktemp\_r, \_mkdtemp\_r, \_mkstemp\_r, \_mkostemp\_r, \_mkostemps\_r, and \_mkstemps\_r are reentrant versions. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

mktemp returns the pointer path to the modified string representing an unused filename, unless it could not generate one, or the pattern you provided is not suitable for a filename; in that case, it returns NULL. Be aware that there is an inherent race between generating the name and attempting to create a file by that name; you are advised to use O\_EXCL|O\_CREAT.

mkdtemp returns the pointer path to the modified string if the directory was created, otherwise it returns NULL.

mkstemp, mkstemps, mkostemp, and mkostemps return a file descriptor to the newly created file, unless it could not generate an unused filename, or the pattern you provided is not suitable for a filename; in that case, it returns -1.

# Portability

ANSI C does not require either mktemp or mkstemp; the System V Interface Definition requires mktemp as of Issue 2. POSIX 2001 requires mkstemp, and POSIX 2008 requires mkdtemp while deprecating mktemp. mkstemps, mkostemp, and mkostemps are not standardized.

Supporting OS subroutines required: getpid, mkdir, open, stat.

# 4.42 open\_memstream, open\_wmemstream—open a write stream around an arbitrary-length string

# Synopsis

#### Description

open\_memstream creates a seekable, byte-oriented FILE stream that wraps an arbitrary-length buffer, created as if by malloc. The current contents of \*buf are ignored; this implementation uses \*size as a hint of the maximum size expected, but does not fail if the hint was wrong. The parameters buf and size are later stored through following any call to fflush or fclose, set to the current address and usable size of the allocated string; although after fflush, the pointer is only valid until another stream operation that results in a write. Behavior is undefined if the user alters either \*buf or \*size prior to fclose.

open\_wmemstream is like open\_memstream just with the associated stream being wideoriented. The size set in size in subsequent operations is the number of wide characters.

The stream is write-only, since the user can directly read \*buf after a flush; see fmemopen for a way to wrap a string with a readable stream. The user is responsible for calling free on the final \*buf after fclose.

Any time the stream is flushed, a NUL byte is written at the current position (but is not counted in the buffer length), so that the string is always NUL-terminated after at most \*size bytes (or wide characters in case of open\_wmemstream). However, data previously written beyond the current stream offset is not lost, and the NUL value written during a flush is restored to its previous value when seeking elsewhere in the string.

#### Returns

The return value is an open FILE pointer on success. On error, NULL is returned, and errno will be set to EINVAL if *buf* or *size* is NULL, ENOMEM if memory could not be allocated, or EMFILE if too many streams are already open.

#### **Portability**

POSIX.1-2008

Supporting OS subroutines required: sbrk.

# 4.43 perror—print an error message on standard error

## **Synopsis**

```
#include <stdio.h>
void perror(char *prefix);

void _perror_r(struct _reent *reent, char *prefix);
```

## Description

Use perror to print (on standard error) an error message corresponding to the current value of the global variable error. Unless you use NULL as the value of the argument prefix, the error message will begin with the string at prefix, followed by a colon and a space (:). The remainder of the error message is one of the strings described for strerror.

The alternate function \_perror\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

perror returns no result.

#### **Portability**

ANSI C requires perror, but the strings issued vary from one implementation to another. Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 4.44 putc—write a character (macro)

# **Synopsis**

```
#include <stdio.h>
int putc(int ch, FILE *fp);

#include <stdio.h>
int _putc_r(struct _reent *ptr, int ch, FILE *fp);
```

#### Description

putc is a macro, defined in stdio.h. putc writes the argument ch to the file or stream identified by fp, after converting it from an int to an unsigned char.

If the file was opened with append mode (or if the stream cannot support positioning), then the new character goes at the end of the file or stream. Otherwise, the new character is written at the current value of the position indicator, and the position indicator advances by one.

For a subroutine version of this macro, see fputc.

The \_putc\_r function is simply the reentrant version of putc that takes an additional reentrant structure argument: ptr.

#### Returns

If successful, putc returns its argument ch. If an error intervenes, the result is EOF. You can use 'ferror(fp)' to query for errors.

#### **Portability**

ANSI C requires putc; it suggests, but does not require, that putc be implemented as a macro. The standard explicitly permits macro implementations of putc to use the fp argument more than once; therefore, in a portable program, you should not use an expression with side effects as this argument.

# 4.45 putc\_unlocked—non-thread-safe version of putc (macro) Synopsis

```
#include <stdio.h>
int putc_unlocked(int ch, FILE *fp);

#include <stdio.h>
int _putc_unlocked_r(struct _reent *ptr, int ch, FILE *fp);
```

# Description

putc\_unlocked is a non-thread-safe version of putc declared in stdio.h. putc\_unlocked may only safely be used within a scope protected by flockfile() (or ftrylockfile()) and funlockfile(). These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE \*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions. If threads are disabled, then putc\_unlocked is equivalent to putc.

The function \_putc\_unlocked\_r is simply the reentrant version of putc\_unlocked that takes an additional reentrant structure pointer argument: ptr.

#### Returns

See putc.

# **Portability**

POSIX 1003.1 requires putc\_unlocked. putc\_unlocked may be implemented as a macro, so arguments should not have side-effects.

# 4.46 putchar—write a character (macro)

# **Synopsis**

```
#include <stdio.h>
int putchar(int ch);
int _putchar_r(struct _reent *reent, int ch);
```

# Description

putchar is a macro, defined in stdio.h. putchar writes its argument to the standard output stream, after converting it from an int to an unsigned char.

The alternate function \_putchar\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

If successful, putchar returns its argument ch. If an error intervenes, the result is EOF. You can use 'ferror(stdin)' to query for errors.

# Portability

ANSI C requires putchar; it suggests, but does not require, that putchar be implemented as a macro.

# 4.47 putchar\_unlocked—non-thread-safe version of putchar (macro)

# Synopsis

```
#include <stdio.h>
int putchar_unlocked(int ch);
```

# Description

putchar\_unlocked is a non-thread-safe version of putchar declared in stdio.h. putchar\_unlocked may only safely be used within a scope protected by flockfile() (or ftrylockfile()) and funlockfile(). These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE \*) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions. If threads are disabled, then putchar\_unlocked is equivalent to putchar.

# Returns

See putchar.

## **Portability**

POSIX 1003.1 requires putchar\_unlocked. putchar\_unlocked may be implemented as a macro.

# 4.48 puts—write a character string

# **Synopsis**

```
#include <stdio.h>
int puts(const char *s);
int _puts_r(struct _reent *reent, const char *s);
```

# Description

 ${\tt puts}$  writes the string at s (followed by a newline, instead of the trailing null) to the standard output stream.

The alternate function <code>\_puts\_r</code> is a reentrant version. The extra argument <code>reent</code> is a pointer to a reentrancy structure.

#### Returns

If successful, the result is a nonnegative integer; otherwise, the result is EOF.

## **Portability**

ANSI C requires puts, but does not specify that the result on success must be 0; any non-negative value is permitted.

# 4.49 putw—write a word (int)

# **Synopsis**

```
#include <stdio.h>
int putw(int w, FILE *fp);
```

# Description

putw is a function, defined in stdio.h. You can use putw to write a word to the file or stream identified by fp. As a side effect, putw advances the file's current position indicator.

## Returns

Zero on success, EOF on failure.

# Portability

putw is a remnant of K&R C; it is not part of any ISO C Standard. fwrite should be used instead. In fact, this implementation of putw is based upon fwrite.

Supporting OS subroutines required: fwrite.

# 4.50 putwchar—write a wide character to standard output Synopsis

```
#include <wchar.h>
wint_t putwchar(wchar_t wc);
wint_t _putwchar_r(struct _reent *reent, wchar_t wc);
```

# Description

The putwchar function or macro is the wide-character equivalent of the putchar function. It writes the wide character wc to stdout.

The alternate function \_putwchar\_r is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

If successful, putwchar returns its argument wc. If an error intervenes, the result is EOF. You can use 'ferror(stdin)' to query for errors.

# Portability

C99

# 4.51 remove—delete a file's name

# **Synopsis**

```
#include <stdio.h>
int remove(char *filename);
int _remove_r(struct _reent *reent, char *filename);
```

# Description

Use remove to dissolve the association between a particular filename (the string at *filename*) and the file it represents. After calling remove with a particular filename, you will no longer be able to open the file by that name.

In this implementation, you may use **remove** on an open file without error; existing file descriptors for the file will continue to access the file's data until the program using them closes the file.

The alternate function <u>\_remove\_r</u> is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

remove returns 0 if it succeeds, -1 if it fails.

### Portability

ANSI C requires remove, but only specifies that the result on failure be nonzero. The behavior of remove when you call it on an open file may vary among implementations.

Supporting OS subroutine required: unlink.

# 4.52 rename—rename a file

# **Synopsis**

```
#include <stdio.h>
int rename(const char *old, const char *new);
```

## Description

Use rename to establish a new name (the string at new) for a file now known by the string at old. After a successful rename, the file is no longer accessible by the string at old.

If rename fails, the file named \*old is unaffected. The conditions for failure depend on the host operating system.

### Returns

The result is either 0 (when successful) or -1 (when the file could not be renamed).

## Portability

ANSI C requires rename, but only specifies that the result on failure be nonzero. The effects of using the name of an existing file as \*new may vary from one implementation to another. Supporting OS subroutines required: link, unlink, or rename.

# 4.53 rewind—reinitialize a file or stream

# **Synopsis**

```
#include <stdio.h>
void rewind(FILE *fp);
void _rewind_r(struct _reent *ptr, FILE *fp);
```

# Description

rewind returns the file position indicator (if any) for the file or stream identified by fp to the beginning of the file. It also clears any error indicator and flushes any pending output.

#### Returns

rewind does not return a result.

# Portability

ANSI C requires rewind.

No supporting OS subroutines are required.

# 4.54 setbuf—specify full buffering for a file or stream

# **Synopsis**

```
#include <stdio.h>
void setbuf(FILE *fp, char *buf);
```

# Description

setbuf specifies that output to the file or stream identified by fp should be fully buffered. All output for this file will go to a buffer (of size BUFSIZ, specified in 'stdio.h'). Output will be passed on to the host system only when the buffer is full, or when an input operation intervenes.

You may, if you wish, supply your own buffer by passing a pointer to it as the argument buf. It must have size BUFSIZ. You can also use NULL as the value of buf, to signal that the setbuf function is to allocate the buffer.

#### Warnings

You may only use **setbuf** before performing any file operation other than opening the file. If you supply a non-null buf, you must ensure that the associated storage continues to be available until you close the stream identified by fp.

#### Returns

setbuf does not return a result.

#### **Portability**

Both ANSI C and the System V Interface Definition (Issue 2) require **setbuf**. However, they differ on the meaning of a NULL buffer pointer: the SVID issue 2 specification says that a NULL buffer pointer requests unbuffered output. For maximum portability, avoid NULL buffer pointers.

# 4.55 setbuffer—specify full buffering for a file or stream with size

# Synopsis

```
#include <stdio.h>
void setbuffer(FILE *fp, char *buf, int size);
```

# Description

setbuffer specifies that output to the file or stream identified by fp should be fully buffered. All output for this file will go to a buffer (of size size). Output will be passed on to the host system only when the buffer is full, or when an input operation intervenes.

You may, if you wish, supply your own buffer by passing a pointer to it as the argument buf. It must have size size. You can also use NULL as the value of buf, to signal that the setbuffer function is to allocate the buffer.

# Warnings

You may only use **setbuffer** before performing any file operation other than opening the file.

If you supply a non-null buf, you must ensure that the associated storage continues to be available until you close the stream identified by fp.

#### Returns

setbuffer does not return a result.

## **Portability**

This function comes from BSD not ANSI or POSIX.

# 4.56 setlinebuf—specify line buffering for a file or stream

# Synopsis

```
#include <stdio.h>
void setlinebuf(FILE *fp);
```

## Description

setlinebuf specifies that output to the file or stream identified by fp should be line buffered. This causes the file or stream to pass on output to the host system at every newline, as well as when the buffer is full, or when an input operation intervenes.

### Warnings

You may only use **setlinebuf** before performing any file operation other than opening the file.

#### Returns

setlinebuf returns as per setvbuf.

# Portability

This function comes from BSD not ANSI or POSIX.

# 4.57 setvbuf—specify file or stream buffering

# **Synopsis**

```
#include <stdio.h>
int setvbuf(FILE *fp, char *buf,
    int mode, size_t size);
```

#### Description

Use **setvbuf** to specify what kind of buffering you want for the file or stream identified by fp, by using one of the following values (from **stdio.h**) as the *mode* argument:

\_IONBF Do not use a buffer: send output directly to the host system for the file or stream identified by fp.

\_IOFBF Use full output buffering: output will be passed on to the host system only when the buffer is full, or when an input operation intervenes.

\_IOLBF Use line buffering: pass on output to the host system at every newline, as well as when the buffer is full, or when an input operation intervenes.

Use the *size* argument to specify how large a buffer you wish. You can supply the buffer itself, if you wish, by passing a pointer to a suitable area of memory as *buf*. Otherwise, you may pass NULL as the *buf* argument, and **setvbuf** will allocate the buffer.

#### Warnings

You may only use **setvbuf** before performing any file operation other than opening the file. If you supply a non-null buf, you must ensure that the associated storage continues to be available until you close the stream identified by fp.

#### Returns

A 0 result indicates success, E0F failure (invalid mode or size can cause failure).

#### **Portability**

Both ANSI C and the System V Interface Definition (Issue 2) require **setvbuf**. However, they differ on the meaning of a NULL buffer pointer: the SVID issue 2 specification says that a NULL buffer pointer requests unbuffered output. For maximum portability, avoid NULL buffer pointers.

Both specifications describe the result on failure only as a nonzero value.

# 4.58 siprintf, fiprintf, iprintf, sniprintf, asiprintf, asiprintf—format output (integer only)

# **Synopsis**

```
#include <stdio.h>
int iprintf(const char *format, ...);
int fiprintf(FILE *fd, const char *format , ...);
int siprintf(char *str, const char *format, ...);
int sniprintf(char *str, size_t size, const char *format,
    ...);
int asiprintf(char **strp, const char *format, ...);
char *asniprintf(char *str, size_t *size,
    const char *format, ...);
int _iprintf_r(struct _reent *ptr, const char *format, ...);
int _fiprintf_r(struct _reent *ptr, FILE *fd,
   const char *format, ...);
int _siprintf_r(struct _reent *ptr, char *str,
   const char *format, ...);
int _sniprintf_r(struct _reent *ptr, char *str, size_t size,
    const char *format, ...);
int _asiprintf_r(struct _reent *ptr, char **strp,
    const char *format, ...);
char *_asniprintf_r(struct _reent *ptr, char *str,
    size_t *size, const char *format, ...);
```

# Description

iprintf, fiprintf, siprintf, sniprintf, asiprintf, and asniprintf are the same as printf, fprintf, sprintf, snprintf, asprintf, and asnprintf, respectively, except that they restrict usage to non-floating-point format specifiers.

\_iprintf\_r, \_fiprintf\_r, \_asiprintf\_r, \_siprintf\_r, \_sniprintf\_r, \_asniprintf\_r are simply reentrant versions of the functions above.

#### Returns

Similar to printf, fprintf, sprintf, snprintf, asprintf, and asprintf.

#### Portability

iprintf, fiprintf, siprintf, sniprintf, asiprintf, and asniprintf are newlib extensions.

# 4.59 siscanf, fiscanf, iscanf—scan and format non-floating input

# Synopsis

#### Description

iscanf, fiscanf, and siscanf are the same as scanf, fscanf, and sscanf respectively, only that they restrict the available formats to non-floating-point format specifiers.

The routines \_iscanf\_r, \_fiscanf\_r, and \_siscanf\_r are reentrant versions of iscanf, fiscanf, and siscanf that take an additional first argument pointing to a reentrancy structure.

#### Returns

iscanf returns the number of input fields successfully scanned, converted and stored; the return value does not include scanned fields which were not stored.

If iscanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

#### **Portability**

iscanf, fiscanf, and siscanf are newlib extensions.

# 4.60 sprintf, fprintf, printf, snprintf, asprintf, asprintf—format output

Synopsis

```
#include <stdio.h>
int printf(const char *format, ...);
int fprintf(FILE *fd, const char *format, ...);
int sprintf(char *str, const char *format, ...);
int snprintf(char *str, size_t size, const char *format,
    ...):
int asprintf(char **strp, const char *format, ...);
char *asnprintf(char *str, size_t *size, const char *format,
    ...);
int _printf_r(struct _reent *ptr, const char *format, ...);
int _fprintf_r(struct _reent *ptr, FILE *fd,
    const char *format, ...);
int _sprintf_r(struct _reent *ptr, char *str,
    const char *format, ...);
int _snprintf_r(struct _reent *ptr, char *str, size_t size,
   const char *format, ...);
int _asprintf_r(struct _reent *ptr, char **strp,
    const char *format, ...);
char *_asnprintf_r(struct _reent *ptr, char *str,
    size_t *size, const char *format, ...);
```

#### Description

printf accepts a series of arguments, applies to each a format specifier from \*format, and writes the formatted data to stdout, without a terminating NUL character. The behavior of printf is undefined if there are not enough arguments for the format. printf returns when it reaches the end of the format string. If there are more arguments than the format requires, excess arguments are ignored.

fprintf is like printf, except that output is directed to the stream fd rather than stdout.

sprintf is like printf, except that output is directed to the buffer str, and a terminating NUL is output. Behavior is undefined if more output is generated than the buffer can hold.

snprintf is like sprintf, except that output is limited to at most size bytes, including the terminating NUL. As a special case, if size is 0, str can be NULL, and snprintf merely calculates how many bytes would be printed.

asprintf is like sprintf, except that the output is stored in a dynamically allocated buffer, pstr, which should be freed later with free.

asnprintf is like sprintf, except that the return type is either the original str if it was large enough, or a dynamically allocated string if the output exceeds \*size; the length of the result is returned in \*size. When dynamic allocation occurs, the contents of the original str may have been modified.

For sprintf, snprintf, and asnprintf, the behavior is undefined if the output \*str overlaps with one of the arguments. Behavior is also undefined if the argument for %n within \*format overlaps another argument.

format is a pointer to a character string containing two types of objects: ordinary characters (other than %), which are copied unchanged to the output, and conversion specifications, each of which is introduced by %. (To include % in the output, use %% in the format string.) A conversion specification has the following form:

%[pos][flags][width][.prec][size]type

The fields of the conversion specification have the following meanings:

#### • pos

Conversions normally consume arguments in the order that they are presented. However, it is possible to consume arguments out of order, and reuse an argument for more than one conversion specification (although the behavior is undefined if the same argument is requested with different types), by specifying pos, which is a decimal integer followed by '\$'. The integer must be between 1 and <NL\_ARGMAX> from limits.h, and if argument %n\$ is requested, all earlier arguments must be requested somewhere within format. If positional parameters are used, then all conversion specifications except for %% must specify a position. This positional parameters method is a POSIX extension to the C standard definition for the functions.

#### flags

flags is an optional sequence of characters which control output justification, numeric signs, decimal points, trailing zeros, and octal and hex prefixes. The flag characters are minus (-), plus (+), space (), zero (0), sharp (#), and quote ('). They can appear in any combination, although not all flags can be used for all conversion specification types.

- A POSIX extension to the C standard. However, this implementation presently treats it as a no-op, which is the default behavior for the C locale, anyway. (If it did what it is supposed to, when type were i, d, u, f, F, g, or G, the integer portion of the conversion would be formatted with thousands' grouping wide characters.)
- The result of the conversion is left justified, and the right is padded with blanks. If you do not use this flag, the result is right justified, and padded on the left.
- + The result of a signed conversion (as determined by type of d, i, a, A, e, E, f, F, g, or G) will always begin with a plus or minus sign. (If you do not use this flag, positive values do not begin with a plus sign.)

# " " (space)

If the first character of a signed conversion specification is not a sign, or if a signed conversion results in no characters, the result will begin with a space. If the space ( ) flag and the plus (+) flag both appear, the space flag is ignored.

O If the type character is d, i, o, u, x, X, a, A, e, E, f, F, g, or G: leading zeros are used to pad the field width (following any indication of sign or

base); no spaces are used for padding. If the zero (0) and minus (-) flags both appear, the zero (0) flag will be ignored. For d, i, o, u, x, and X conversions, if a precision prec is specified, the zero (0) flag is ignored.

Note that 0 is interpreted as a flag, not as the beginning of a field width.

# The result is to be converted to an alternative form, according to the *type* character:

o Increases precision to force the first digit of the result to be a zero.

x A non-zero result will have a 0x prefix.

X A non-zero result will have a OX prefix.

a, A, e, E, f, or F

The result will always contain a decimal point even if no digits follow the point. (Normally, a decimal point appears only if a digit follows it.) Trailing zeros are removed.

g or G The result will always contain a decimal point even if no digits follow the point. Trailing zeros are not removed.

all others

Undefined.

#### • width

width is an optional minimum field width. You can either specify it directly as a decimal integer, or indirectly by using instead an asterisk (\*), in which case an int argument is used as the field width. If positional arguments are used, then the width must also be specified positionally as \*m\$, with m as a decimal integer. Negative field widths are treated as specifying the minus (-) flag for left justfication, along with a positive field width. The resulting format may be wider than the specified width.

#### prec

prec is an optional field; if present, it is introduced with '.' (a period). You can specify the precision either directly as a decimal integer or indirectly by using an asterisk (\*), in which case an int argument is used as the precision. If positional arguments are used, then the precision must also be specified positionally as \*m\$, with m as a decimal integer. Supplying a negative precision is equivalent to omitting the precision. If only a period is specified the precision is zero. The effect depends on the conversion type.

#### d, i, o, u, x, or X

Minimum number of digits to appear. If no precision is given, defaults to 1.

a or A Number of digits to appear after the decimal point. If no precision is given, the precision defaults to the minimum needed for an exact representation.

# e, E, f or F

Number of digits to appear after the decimal point. If no precision is given, the precision defaults to 6.

g or G Maximum number of significant digits. A precision of 0 is treated the same as a precision of 1. If no precision is given, the precision defaults to 6.

s or S Maximum number of characters to print from the string. If no precision is given, the entire string is printed.

#### all others

undefined.

#### size

size is an optional modifier that changes the data type that the corresponding argument has. Behavior is unspecified if a size is given that does not match the *type*.

with d, i, o, u, x, or X, specifies that the argument should be converted to a signed char or unsigned char before printing.

With n, specifies that the argument is a pointer to a signed char.

h With d, i, o, u, x, or X, specifies that the argument should be converted to a short or unsigned short before printing.

With n, specifies that the argument is a pointer to a short.

With d, i, o, u, x, or X, specifies that the argument is a long or unsigned long.

With c, specifies that the argument has type wint\_t.

With s, specifies that the argument is a pointer to wchar\_t.

With n, specifies that the argument is a pointer to a long.

With a, A, e, E, f, F, g, or G, has no effect (because of vararg promotion rules, there is no need to distinguish between float and double).

With d, i, o, u, x, or X, specifies that the argument is a long long or unsigned long long.

With n, specifies that the argument is a pointer to a long long.

j With d, i, o, u, x, or X, specifies that the argument is an intmax\_t or uintmax\_t.

With n, specifies that the argument is a pointer to an intmax\_t.

- With d, i, o, u, x, or X, specifies that the argument is a size\_t.With n, specifies that the argument is a pointer to a size\_t.
- t With d, i, o, u, x, or X, specifies that the argument is a ptrdiff\_t.

  With n, specifies that the argument is a pointer to a ptrdiff\_t.
- L With a, A, e, E, f, F, g, or G, specifies that the argument is a long double.

#### • type

type specifies what kind of conversion printf performs. Here is a table of these:

- % Prints the percent character (%).
- c Prints arg as single character. If the 1 size specifier is in effect, a multibyte character is printed.
- C Short for %lc. A POSIX extension to the C standard.

- s Prints the elements of a pointer to char until the precision or a null character is reached. If the 1 size specifier is in effect, the pointer is to an array of wchar\_t, and the string is converted to multibyte characters before printing.
- S Short for %1s. A POSIX extension to the C standard.
- d or i Prints a signed decimal integer; takes an int. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- D Newlib extension, short for %ld.
- o Prints an unsigned octal integer; takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- O Newlib extension, short for %lo.
- u Prints an unsigned decimal integer; takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- U Newlib extension, short for %lu.
- x Prints an unsigned hexadecimal integer (using abcdef as digits beyond 9); takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- X Like x, but uses ABCDEF as digits beyond 9.
- Prints a signed value of the form [-]9999.9999, with the precision determining how many digits follow the decimal point; takes a double (remember that float promotes to double as a vararg). The low order digit is rounded to even. If the precision results in at most DECIMAL\_DIG digits, the result is rounded correctly; if more than DECIMAL\_DIG digits are printed, the result is only guaranteed to round back to the original value. If the value is infinite, the result is inf, and no zero padding is performed. If the value is not a number, the result is nan, and no zero padding is performed.
- F Like f, but uses INF and NAN for non-finite numbers.
- e Prints a signed value of the form [-]9.9999e[+|-]999; takes a double. The digit before the decimal point is non-zero if the value is non-zero. The precision determines how many digits appear between . and e, and the exponent always contains at least two digits. The value zero has an exponent of zero. If the value is not finite, it is printed like f.
- E Like e, but using E to introduce the exponent, and like F for non-finite values.
- g Prints a signed value in either f or e form, based on the given value and precision—an exponent less than -4 or greater than the precision selects the e form. Trailing zeros and the decimal point are printed only if necessary; takes a double.

- G Like g, except use F or E form.
- a Prints a signed value of the form [-]0x1.ffffp[+|-]9; takes a double. The letters abcdef are used for digits beyond 9. The precision determines how many digits appear after the decimal point. The exponent contains at least one digit, and is a decimal value representing the power of 2; a value of 0 has an exponent of 0. Non-finite values are printed like f.
- A Like a, except uses X, P, and ABCDEF instead of lower case.
- n Takes a pointer to int, and stores a count of the number of bytes written so far. No output is created.
- Takes a pointer to void, and prints it in an implementation-defined format. This implementation is similar to %#tx), except that 0x appears even for the NULL pointer.
- m Prints the output of strerror(errno); no argument is required. A GNU extension.

\_printf\_r, \_fprintf\_r, \_asprintf\_r, \_sprintf\_r, \_snprintf\_r, \_asnprintf\_r are simply reentrant versions of the functions above.

#### Returns

On success, sprintf and asprintf return the number of bytes in the output string, except the concluding NUL is not counted. snprintf returns the number of bytes that would be in the output string, except the concluding NUL is not counted. printf and fprintf return the number of characters transmitted. asnprintf returns the original str if there was enough room, otherwise it returns an allocated string.

If an error occurs, the result of printf, fprintf, snprintf, and asprintf is a negative value, and the result of asnprintf is NULL. No error returns occur for sprintf. For printf and fprintf, errno may be set according to fputc. For asprintf and asnprintf, errno may be set to ENOMEM if allocation fails, and for snprintf, errno may be set to EOVERFLOW if size or the output length exceeds INT\_MAX.

#### Bugs

The "" (quote) flag does not work when locale's thousands\_sep is not empty.

#### Portability

ANSI C requires printf, fprintf, sprintf, and snprintf. asprintf and asprintf are newlib extensions.

The ANSI C standard specifies that implementations must support at least formatted output of up to 509 characters. This implementation has no inherent limit.

Depending on how newlib was configured, not all format specifiers are supported.

# 4.61 sscanf, fscanf, scanf—scan and format input Synopsis

# Description

scanf scans a series of input fields from standard input, one character at a time. Each field is interpreted according to a format specifier passed to scanf in the format string at \*format. scanf stores the interpreted input from each field at the address passed to it as the corresponding argument following format. You must supply the same number of format specifiers and address arguments as there are input fields.

There must be sufficient address arguments for the given format specifiers; if not the results are unpredictable and likely disasterous. Excess address arguments are merely ignored.

scanf often produces unexpected results if the input diverges from an expected pattern. Since the combination of gets or fgets followed by sscanf is safe and easy, that is the preferred way to be certain that a program is synchronized with input at the end of a line. fscanf and sscanf are identical to scanf, other than the source of input: fscanf reads from a file, and sscanf from a string.

The routines \_scanf\_r, \_fscanf\_r, and \_sscanf\_r are reentrant versions of scanf, fscanf, and sscanf that take an additional first argument pointing to a reentrancy structure.

The string at \*format is a character sequence composed of zero or more directives. Directives are composed of one or more whitespace characters, non-whitespace characters, and format specifications.

Whitespace characters are blank (), tab (\t), or newline (\n). When scanf encounters a whitespace character in the format string it will read (but not store) all consecutive whitespace characters up to the next non-whitespace character in the input.

Non-whitespace characters are all other ASCII characters except the percent sign (%). When scanf encounters a non-whitespace character in the format string it will read, but not store a matching non-whitespace character.

Format specifications tell **scanf** to read and convert characters from the input field into specific types of values, and store then in the locations specified by the address arguments.

Trailing whitespace is left unread unless explicitly matched in the format string.

The format specifiers must begin with a percent sign (%) and have the following form: %[\*][width][size]type

Each format specification begins with the percent character (%). The other fields are:

size

\* an optional marker; if present, it suppresses interpretation and assignment of this input field.

an optional maximum field width: a decimal integer, which controls the maximum number of characters that will be read before converting the current input field. If the input field has fewer than width characters, scanf reads all the characters in the field, and then proceeds with the next field and its format specification.

If a whitespace or a non-convertable character occurs before width character are read, the characters up to that character are read, converted, and stored. Then scanf proceeds to the next format specification.

h, j, l, L, t, and z are optional size characters which override the default way that scanf interprets the data type of the corresponding argument.

		1 0 0
odifier	Type(s)	
hh	d, i, o, u, x, n	convert input to char, store in char object
h	d, i, o, u, x, n	convert input to short, store in short object
h	D, I, O, U, X e, f, c, s, p	no effect
j	d, i, o, u, x, n	<pre>convert input to intmax_t, store in intmax_t object</pre>
j	all others	no effect
1	d, i, o, u, x, n	convert input to long, store in long object
1	e, f, g	convert input to double store in a double object
1	D, I, O, U, X c, s, p	no effect
11	d, i, o, u, x, n	convert to long long, store in long long
L	d, i, o, u, x, n	convert to long long, store in long long
L	e, f, g, E, G	convert to long double, store in long double
L	all others	no effect
t	d, i, o, u, x, n	<pre>convert input to ptrdiff_t, store in ptrdiff_t object</pre>
t	all others	no effect
z	d, i, o, u, x, n	convert input to size_t, store in size_t object

#### z all others no effect

#### type

A character to specify what kind of conversion scanf performs. Here is a table of the conversion characters:

- % No conversion is done; the percent character (%) is stored.
- c Scans one character. Corresponding arg: (char \*arg).
- s Reads a character string into the array supplied. Corresponding arg: (char arg[]).

#### [pattern]

Reads a non-empty character string into memory starting at arg. This area must be large enough to accept the sequence and a terminating null character which will be added automatically. (pattern is discussed in the paragraph following this table). Corresponding arg: (char \*arg).

- d Reads a decimal integer into the corresponding arg: (int \*arg).
- D Reads a decimal integer into the corresponding arg: (long \*arg).
- o Reads an octal integer into the corresponding arg: (int \*arg).
- O Reads an octal integer into the corresponding arg: (long \*arg).
- u Reads an unsigned decimal integer into the corresponding arg: (unsigned int \*arg).
- U Reads an unsigned decimal integer into the corresponding arg: (unsigned long \*arg).
- x,X Read a hexadecimal integer into the corresponding arg: (int \*arg).
- e, f, g Read a floating-point number into the corresponding arg: (float \*arg).
- E, F, G Read a floating-point number into the corresponding arg: (double \*arg).
- i Reads a decimal, octal or hexadecimal integer into the corresponding arg: (int \*arg).
- I Reads a decimal, octal or hexadecimal integer into the corresponding arg: (long \*arg).
- n Stores the number of characters read in the corresponding arg: (int \*arg).
- p Stores a scanned pointer. ANSI C leaves the details to each implementation; this implementation treats %p exactly the same as %U. Corresponding arg: (void \*\*arg).

A pattern of characters surrounded by square brackets can be used instead of the s type character. pattern is a set of characters which define a search set of possible characters making up the scanf input field. If the first character in the brackets is a caret (^), the search set is inverted to include all ASCII characters except those between the brackets. There is also a range facility which you can use as a shortcut. %[0-9] matches all decimal digits. The hyphen must not be the first or last character in the set. The character prior to the hyphen must be lexically less than the character after it.

Here are some pattern examples:

"[abcd] matches strings containing only a, b, c, and d.

%[^abcd] matches strings containing any characters except a, b, c, or d

%[A-DW-Z]

matches strings containing A, B, C, D, W, X, Y, Z

%[z-a] matches the characters z, -, and a

Floating point numbers (for field types e, f, g, E, F, G) must correspond to the following general form:

```
[+/-] ddddd[.]ddd [E|e[+|-]ddd]
```

where objects inclosed in square brackets are optional, and ddd represents decimal, octal, or hexadecimal digits.

## Returns

scanf returns the number of input fields successfully scanned, converted and stored; the return value does not include scanned fields which were not stored.

If scanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

scanf might stop scanning a particular field before reaching the normal field end character, or may terminate entirely.

scanf stops scanning and storing the current field and moves to the next input field (if any) in any of the following situations:

- The assignment suppressing character (\*) appears after the % in the format specification; the current input field is scanned but not stored.
- width characters have been read (width is a width specification, a positive decimal integer).
- The next character read cannot be converted under the the current format (for example, if a Z is read when the format is decimal).
- The next character in the input field does not appear in the search set (or does appear in the inverted search set).

When scanf stops scanning the current input field for one of these reasons, the next character is considered unread and used as the first character of the following input field, or the first character in a subsequent read operation on the input.

scanf will terminate under the following circumstances:

- The next character in the input field conflicts with a corresponding non-whitespace character in the format string.
- The next character in the input field is EOF.
- The format string has been exhausted.

When the format string contains a character sequence that is not part of a format specification, the same character sequence must appear in the input; scanf will scan but not store the matched characters. If a conflict occurs, the first conflicting character remains in the input as if it had never been read.

### **Portability**

scanf is ANSI C.

# 4.62 swprintf, fwprintf, wprintf—wide character format output

# Synopsis

# Description

wprintf accepts a series of arguments, applies to each a format specifier from \*format, and writes the formatted data to stdout, without a terminating NUL wide character. The behavior of wprintf is undefined if there are not enough arguments for the format or if any argument is not the right type for the corresponding conversion specifier. wprintf returns when it reaches the end of the format string. If there are more arguments than the format requires, excess arguments are ignored.

fwprintf is like wprintf, except that output is directed to the stream fd rather than stdout.

swprintf is like wprintf, except that output is directed to the buffer str with a terminating wide NUL, and the resulting string length is limited to at most size wide characters, including the terminating NUL. It is considered an error if the output (including the terminating wide-NULL) does not fit into size wide characters. (This error behavior is not the same as for snprintf, which swprintf is otherwise completely analogous to. While snprintf allows the needed size to be known simply by giving size=0, swprintf does not, giving an error instead.)

For swprintf the behavior is undefined if the output \*str overlaps with one of the arguments. Behavior is also undefined if the argument for %n within \*format overlaps another argument.

format is a pointer to a wide character string containing two types of objects: ordinary characters (other than %), which are copied unchanged to the output, and conversion specifications, each of which is introduced by %. (To include % in the output, use %% in the format string.) A conversion specification has the following form:

```
%[pos][flags][width][.prec][size]type
```

The fields of the conversion specification have the following meanings:

pos

Conversions normally consume arguments in the order that they are presented. However, it is possible to consume arguments out of order, and reuse an argument for more than one conversion specification (although the behavior is undefined if the same argument is requested with different types), by specifying pos, which is a decimal integer followed by '\$'. The integer must be between 1 and <NL\_ARGMAX> from limits.h, and if argument %n\$ is requested, all earlier arguments must be requested somewhere within format. If positional parameters are used, then all conversion specifications except for %% must specify a position. This positional parameters method is a POSIX extension to the C standard definition for the functions.

#### flags

flags is an optional sequence of characters which control output justification, numeric signs, decimal points, trailing zeros, and octal and hex prefixes. The flag characters are minus (-), plus (+), space (), zero (0), sharp (#), and quote ('). They can appear in any combination, although not all flags can be used for all conversion specification types.

- A POSIX extension to the C standard. However, this implementation presently treats it as a no-op, which is the default behavior for the C locale, anyway. (If it did what it is supposed to, when type were i, d, u, f, F, g, or G, the integer portion of the conversion would be formatted with thousands' grouping wide characters.)
- The result of the conversion is left justified, and the right is padded with blanks. If you do not use this flag, the result is right justified, and padded on the left.
- + The result of a signed conversion (as determined by type of d, i, a, A, e, E, f, F, g, or G) will always begin with a plus or minus sign. (If you do not use this flag, positive values do not begin with a plus sign.)

# " " (space)

If the first character of a signed conversion specification is not a sign, or if a signed conversion results in no characters, the result will begin with a space. If the space ( ) flag and the plus (+) flag both appear, the space flag is ignored.

If the type character is d, i, o, u, x, X, a, A, e, E, f, F, g, or G: leading zeros are used to pad the field width (following any indication of sign or base); no spaces are used for padding. If the zero (0) and minus (-) flags both appear, the zero (0) flag will be ignored. For d, i, o, u, x, and X conversions, if a precision prec is specified, the zero (0) flag is ignored.

Note that 0 is interpreted as a flag, not as the beginning of a field width.

- # The result is to be converted to an alternative form, according to the *type* character:
  - o Increases precision to force the first digit of the result to be a zero.
  - x A non-zero result will have a 0x prefix.
  - X A non-zero result will have a OX prefix.

# a, A, e, E, f, or F

The result will always contain a decimal point even if no digits follow the point. (Normally, a decimal point appears only if a digit follows it.) Trailing zeros are removed. g or G The result will always contain a decimal point even if no digits follow the point. Trailing zeros are not removed.

#### all others

Undefined.

#### • width

width is an optional minimum field width. You can either specify it directly as a decimal integer, or indirectly by using instead an asterisk (\*), in which case an int argument is used as the field width. If positional arguments are used, then the width must also be specified positionally as \*m\$, with m as a decimal integer. Negative field widths are treated as specifying the minus (-) flag for left justfication, along with a positive field width. The resulting format may be wider than the specified width.

# prec

prec is an optional field; if present, it is introduced with '.' (a period). You can specify the precision either directly as a decimal integer or indirectly by using an asterisk (\*), in which case an int argument is used as the precision. If positional arguments are used, then the precision must also be specified positionally as \*m\$, with m as a decimal integer. Supplying a negative precision is equivalent to omitting the precision. If only a period is specified the precision is zero. The effect depends on the conversion type.

#### d, i, o, u, x, or X

Minimum number of digits to appear. If no precision is given, defaults to 1

a or A Number of digits to appear after the decimal point. If no precision is given, the precision defaults to the minimum needed for an exact representation.

#### e, E, f or F

Number of digits to appear after the decimal point. If no precision is given, the precision defaults to 6.

- g or G Maximum number of significant digits. A precision of 0 is treated the same as a precision of 1. If no precision is given, the precision defaults to 6.
- s or S Maximum number of characters to print from the string. If no precision is given, the entire string is printed.

#### all others

undefined.

#### size

size is an optional modifier that changes the data type that the corresponding argument has. Behavior is unspecified if a size is given that does not match the type.

hh With d, i, o, u, x, or X, specifies that the argument should be converted to a signed char or unsigned char before printing.

With n, specifies that the argument is a pointer to a signed char.

h With d, i, o, u, x, or X, specifies that the argument should be converted to a short or unsigned short before printing.

With n, specifies that the argument is a pointer to a short.

With d, i, o, u, x, or X, specifies that the argument is a long or unsigned long.

With c, specifies that the argument has type wint\_t.

With s, specifies that the argument is a pointer to wchar\_t.

With n, specifies that the argument is a pointer to a long.

With a, A, e, E, f, F, g, or G, has no effect (because of vararg promotion rules, there is no need to distinguish between float and double).

With d, i, o, u, x, or X, specifies that the argument is a long long or unsigned long long.

With n, specifies that the argument is a pointer to a long long.

j With d, i, o, u, x, or X, specifies that the argument is an intmax\_t or uintmax\_t.

With n, specifies that the argument is a pointer to an intmax\_t.

With d, i, o, u, x, or X, specifies that the argument is a size\_t.With n, specifies that the argument is a pointer to a size\_t.

With d, i, o, u, x, or X, specifies that the argument is a ptrdiff\_t.

With n, specifies that the argument is a pointer to a ptrdiff\_t.

L With a, A, e, E, f, F, g, or G, specifies that the argument is a long double.

#### • type

t

type specifies what kind of conversion wprintf performs. Here is a table of these:

- % Prints the percent character (%).
- c If no 1 qualifier is present, the int argument shall be converted to a wide character as if by calling the btowc() function and the resulting wide character shall be written. Otherwise, the wint\_t argument shall be converted to wchar\_t, and written.
- C Short for %1c. A POSIX extension to the C standard.
- If no 1 qualifier is present, the application shall ensure that the argument is a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array shall be converted as if by repeated calls to the mbrtowc() function, with the conversion state described by an mbstate\_t object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide character. If the precision is specified, no more than that many wide characters shall be written. If the precision is not specified, or is greater than the size of the array, the application shall ensure that the array contains a null wide character.

If an 1 qualifier is present, the application shall ensure that the argument is a pointer to an array of type wchar\_t. Wide characters from the array shall be written up to (but not including) a terminating null wide character. If no precision is specified, or is greater than the size of the array, the application shall ensure that the array contains a null wide character. If a precision is specified, no more than that many wide characters shall be written.

- S Short for %1s. A POSIX extension to the C standard.
- d or i Prints a signed decimal integer; takes an int. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- o Prints an unsigned octal integer; takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- u Prints an unsigned decimal integer; takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- x Prints an unsigned hexadecimal integer (using abcdef as digits beyond 9); takes an unsigned. Leading zeros are inserted as necessary to reach the precision. A value of 0 with a precision of 0 produces an empty string.
- X Like x, but uses ABCDEF as digits beyond 9.
- Prints a signed value of the form [-]9999.9999, with the precision determining how many digits follow the decimal point; takes a double (remember that float promotes to double as a vararg). The low order digit is rounded to even. If the precision results in at most DECIMAL\_DIG digits, the result is rounded correctly; if more than DECIMAL\_DIG digits are printed, the result is only guaranteed to round back to the original value. If the value is infinite, the result is inf, and no zero padding is performed. If the value is not a number, the result is nan, and no zero padding is performed.
- F Like f, but uses INF and NAN for non-finite numbers.
- e Prints a signed value of the form [-]9.9999e[+|-]999; takes a double. The digit before the decimal point is non-zero if the value is non-zero. The precision determines how many digits appear between . and e, and the exponent always contains at least two digits. The value zero has an exponent of zero. If the value is not finite, it is printed like f.
- E Like e, but using E to introduce the exponent, and like F for non-finite values.
- g Prints a signed value in either f or e form, based on the given value and precision—an exponent less than -4 or greater than the precision selects the e form. Trailing zeros and the decimal point are printed only if necessary; takes a double.
- G Like g, except use F or E form.
- a Prints a signed value of the form [-]0x1.ffffp[+|-]9; takes a double. The letters abcdef are used for digits beyond 9. The precision determines how many digits appear after the decimal point. The exponent contains at least one digit, and is a decimal value representing the power of 2; a value of 0 has an exponent of 0. Non-finite values are printed like f.

- A Like a, except uses X, P, and ABCDEF instead of lower case.
- n Takes a pointer to int, and stores a count of the number of bytes written so far. No output is created.
- Takes a pointer to void, and prints it in an implementation-defined format. This implementation is similar to %#tx), except that 0x appears even for the NULL pointer.
- m Prints the output of strerror(errno); no argument is required. A GNU extension.

\_wprintf\_r, \_fwprintf\_r, \_swprintf\_r, are simply reentrant versions of the functions above.

#### Returns

On success, swprintf return the number of wide characters in the output string, except the concluding NUL is not counted. wprintf and fwprintf return the number of characters transmitted.

If an error occurs, the result of wprintf, fwprintf, and swprintf is a negative value. For wprintf and fwprintf, errno may be set according to fputwc. For swprintf, errno may be set to EOVERFLOW if size is greater than INT\_MAX / sizeof (wchar\_t), or when the output does not fit into size wide characters (including the terminating wide NULL).

#### Bugs

The ""' (quote) flag does not work when locale's thousands\_sep is not empty.

#### Portability

POSIX-1.2008 with extensions; C99 (compliant except for POSIX extensions).

Depending on how newlib was configured, not all format specifiers are supported.

# 4.63 swscanf, fwscanf, wscanf—scan and format wide character input

# **Synopsis**

### Description

wscanf scans a series of input fields from standard input, one wide character at a time. Each field is interpreted according to a format specifier passed to wscanf in the format string at \*format. wscanf stores the interpreted input from each field at the address passed to it as the corresponding argument following format. You must supply the same number of format specifiers and address arguments as there are input fields.

There must be sufficient address arguments for the given format specifiers; if not the results are unpredictable and likely disasterous. Excess address arguments are merely ignored.

wscanf often produces unexpected results if the input diverges from an expected pattern. Since the combination of gets or fgets followed by swscanf is safe and easy, that is the preferred way to be certain that a program is synchronized with input at the end of a line.

fwscanf and swscanf are identical to wscanf, other than the source of input: fwscanf reads from a file, and swscanf from a string.

The routines \_wscanf\_r, \_fwscanf\_r, and \_swscanf\_r are reentrant versions of wscanf, fwscanf, and swscanf that take an additional first argument pointing to a reentrancy structure.

The string at \*format is a wide character sequence composed of zero or more directives. Directives are composed of one or more whitespace characters, non-whitespace characters, and format specifications.

Whitespace characters are blank (), tab (\t), or newline (\n). When wscanf encounters a whitespace character in the format string it will read (but not store) all consecutive whitespace characters up to the next non-whitespace character in the input.

Non-whitespace characters are all other ASCII characters except the percent sign (%). When wscanf encounters a non-whitespace character in the format string it will read, but not store a matching non-whitespace character.

Format specifications tell wscanf to read and convert characters from the input field into specific types of values, and store then in the locations specified by the address arguments.

Trailing whitespace is left unread unless explicitly matched in the format string.

The format specifiers must begin with a percent sign (%) and have the following form:

#### %[\*][width][size]type

Each format specification begins with the percent character (%). The other fields are:

\* an optional marker; if present, it suppresses interpretation and assignment of this input field.

an optional maximum field width: a decimal integer, which controls the maximum number of characters that will be read before converting the current input field. If the input field has fewer than width characters, wscanf reads all the characters in the field, and then proceeds with the next field and its format specification.

If a whitespace or a non-convertable wide character occurs before width character are read, the characters up to that character are read, converted, and stored. Then wscanf proceeds to the next format specification.

h, j, l, L, t, and z are optional size characters which override the default way that wscanf interprets the data type of the corresponding argument.

5	scan interprets the data type of the corresponding argument.				
Мо	Modifier Type(s)				
	hh	d, i, o, u, x, n	convert input to char, store in char object		
	h	d, i, o, u, x, n	convert input to short, store in short object		
	h	e, f, c, s, p	no effect		
	j	d, i, o, u, x, n	<pre>convert input to intmax_t, store in intmax_t object</pre>		
	j	all others	no effect		
	1	d, i, o, u, x, n	convert input to long, store in long object		
	1	e, f, g	convert input to double store in a double object		
	1	c, s, [	the input is stored in a wchar_t object		
	1	p	no effect		
	11	d, i, o, u, x, n	convert to long long, store in long long		
	L	d, i, o, u, x, n	convert to long long, store in long long		
	L	e, f, g, E, G	convert to long double, store in long double		
	L	all others	no effect		
	t	d, i, o, u, x, n	<pre>convert input to ptrdiff_t, store in ptrdiff_t object</pre>		
	t	all others	no effect		

- z d, i, o, u, x, n convert input to size\_t, store in size\_t object
- z all others no effect

#### type

A character to specify what kind of conversion wscanf performs. Here is a table of the conversion characters:

- % No conversion is done; the percent character (%) is stored.
- c Scans one wide character. Corresponding arg: (char \*arg).

  Otherwise, if an 1 specifier is present, the corresponding arg is a (wchar\_t \*arg).
- s Reads a character string into the array supplied. Corresponding arg: (char arg[]). If an 1 specifier is present, the corresponding arg is a (wchar\_t \*arg).

### [pattern]

Reads a non-empty character string into memory starting at arg. This area must be large enough to accept the sequence and a terminating null character which will be added automatically. (pattern is discussed in the paragraph following this table). Corresponding arg: (char \*arg). If an 1 specifier is present, the corresponding arg is a (wchar\_t \*arg).

- d Reads a decimal integer into the corresponding arg: (int \*arg).
- o Reads an octal integer into the corresponding arg: (int \*arg).
- u Reads an unsigned decimal integer into the corresponding arg: (unsigned int \*arg).
- x,X Read a hexadecimal integer into the corresponding arg: (int \*arg).
- e, f, g Read a floating-point number into the corresponding arg: (float \*arg).
- E, F, G Read a floating-point number into the corresponding arg: (double \*arg).
- i Reads a decimal, octal or hexadecimal integer into the corresponding arg: (int \*arg).
- n Stores the number of characters read in the corresponding arg: (int \*arg).
- p Stores a scanned pointer. ANSI C leaves the details to each implementation; this implementation treats %p exactly the same as %U. Corresponding arg: (void \*\*arg).

A pattern of characters surrounded by square brackets can be used instead of the s type character. pattern is a set of characters which define a search set of possible characters making up the wscanf input field. If the first character in the brackets is a caret (^), the search set is inverted to include all ASCII characters except those between the brackets. There is no range facility as is defined in the corresponding non-wide character scanf functions. Ranges are not part of the POSIX standard.

Here are some pattern examples:

%[abcd] matches wide character strings containing only a, b, c, and d.

%[^abcd] matches wide character strings containing any characters except a,
b, c, or d.

%[A-DW-Z]

Note: No wide character ranges, so this expression matches wide character strings containing A, -, D, W, Z.

Floating point numbers (for field types e, f, g, E, F, G) must correspond to the following general form:

[+/-] ddddd[.]ddd [E|e[+|-]ddd]

where objects inclosed in square brackets are optional, and ddd represents decimal, octal, or hexadecimal digits.

#### Returns

wscanf returns the number of input fields successfully scanned, converted and stored; the return value does not include scanned fields which were not stored.

If wscanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

wscanf might stop scanning a particular field before reaching the normal field end character, or may terminate entirely.

wscanf stops scanning and storing the current field and moves to the next input field (if any) in any of the following situations:

- The assignment suppressing character (\*) appears after the % in the format specification; the current input field is scanned but not stored.
- width characters have been read (width is a width specification, a positive decimal integer).
- The next wide character read cannot be converted under the the current format (for example, if a Z is read when the format is decimal).
- The next wide character in the input field does not appear in the search set (or does appear in the inverted search set).

When wscanf stops scanning the current input field for one of these reasons, the next character is considered unread and used as the first character of the following input field, or the first character in a subsequent read operation on the input.

wscanf will terminate under the following circumstances:

- The next wide character in the input field conflicts with a corresponding non-whitespace character in the format string.
- The next wide character in the input field is WEOF.
- The format string has been exhausted.

When the format string contains a wide character sequence that is not part of a format specification, the same wide character sequence must appear in the input; wscanf will scan but not store the matched characters. If a conflict occurs, the first conflicting wide character remains in the input as if it had never been read.

#### **Portability**

wscanf is C99, POSIX-1.2008.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 4.64 tmpfile—create a temporary file

## Synopsis

```
#include <stdio.h>
FILE *tmpfile(void);

FILE *_tmpfile_r(struct _reent *reent);
```

## Description

Create a temporary file (a file which will be deleted automatically), using a name generated by tmpnam. The temporary file is opened with the mode "wb+", permitting you to read and write anywhere in it as a binary file (without any data transformations the host system may perform for text files).

The alternate function \_tmpfile\_r is a reentrant version. The argument reent is a pointer to a reentrancy structure.

#### Returns

tmpfile normally returns a pointer to the temporary file. If no temporary file could be created, the result is NULL, and errno records the reason for failure.

#### Portability

Both ANSI C and the System V Interface Definition (Issue 2) require tmpfile.

Supporting OS subroutines required: close, fstat, getpid, isatty, lseek, open, read, sbrk, write.

tmpfile also requires the global pointer environ.

# 4.65 tmpnam, tempnam—name for a temporary file

## **Synopsis**

```
#include <stdio.h>
char *tmpnam(char *s);
char *tempnam(char *dir, char *pfx);
char *_tmpnam_r(struct _reent *reent, char *s);
char *_tempnam_r(struct _reent *reent, char *dir, char *pfx);
```

#### Description

Use either of these functions to generate a name for a temporary file. The generated name is guaranteed to avoid collision with other files (for up to TMP\_MAX calls of either function). tmpnam generates file names with the value of P\_tmpdir (defined in 'stdio.h') as the leading directory component of the path.

You can use the tmpnam argument s to specify a suitable area of memory for the generated filename; otherwise, you can call tmpnam(NULL) to use an internal static buffer.

tempnam allows you more control over the generated filename: you can use the argument dir to specify the path to a directory for temporary files, and you can use the argument pfx to specify a prefix for the base filename.

If dir is NULL, tempnam will attempt to use the value of environment variable TMPDIR instead; if there is no such value, tempnam uses the value of P\_tmpdir (defined in 'stdio.h').

If you don't need any particular prefix to the basename of temporary files, you can pass  $\mathtt{NULL}$  as the pfx argument to  $\mathtt{tempnam}$ .

\_tmpnam\_r and \_tempnam\_r are reentrant versions of tmpnam and tempnam respectively. The extra argument reent is a pointer to a reentrancy structure.

#### Warnings

The generated filenames are suitable for temporary files, but do not in themselves make files temporary. Files with these names must still be explicitly removed when you no longer want them.

If you supply your own data area s for tmpnam, you must ensure that it has room for at least L\_tmpnam elements of type char.

#### Returns

Both tmpnam and tempnam return a pointer to the newly generated filename.

#### Portability

ANSI C requires tmpnam, but does not specify the use of P\_tmpdir. The System V Interface Definition (Issue 2) requires both tmpnam and tempnam.

Supporting OS subroutines required: close, fstat, getpid, isatty, lseek, open, read, sbrk, write.

The global pointer environ is also required.

# 4.66 ungetc—push data back into a stream

#### **Synopsis**

```
#include <stdio.h>
int ungetc(int c, FILE *stream);
int _ungetc_r(struct _reent *reent, int c, FILE *stream);
```

## Description

ungetc is used to return bytes back to stream to be read again. If c is EOF, the stream is unchanged. Otherwise, the unsigned char c is put back on the stream, and subsequent reads will see the bytes pushed back in reverse order. Pushed bytes are lost if the stream is repositioned, such as by fseek, fsetpos, or rewind.

The underlying file is not changed, but it is possible to push back something different than what was originally read. Ungetting a character will clear the end-of-stream marker, and decrement the file position indicator. Pushing back beyond the beginning of a file gives unspecified behavior.

The alternate function <u>\_ungetc\_r</u> is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The character pushed back, or EOF on error.

#### **Portability**

ANSI C requires ungetc, but only requires a pushback buffer of one byte; although this implementation can handle multiple bytes, not all can. Pushing back a signed char is a common application bug.

Supporting OS subroutines required: sbrk.

# 4.67 ungetwc—push wide character data back into a stream Synopsis

```
#include <stdio.h>
#include <wchar.h>
wint_t ungetwc(wint_t wc, FILE *stream);
wint_t _ungetwc_r(struct _reent *reent, wint_t wc, FILE *stream);
```

#### Description

ungetwo is used to return wide characters back to *stream* to be read again. If wo is WEOF, the stream is unchanged. Otherwise, the wide character wo is put back on the stream, and subsequent reads will see the wide chars pushed back in reverse order. Pushed wide chars are lost if the stream is repositioned, such as by fseek, fsetpos, or rewind.

The underlying file is not changed, but it is possible to push back something different than what was originally read. Ungetting a character will clear the end-of-stream marker, and decrement the file position indicator. Pushing back beyond the beginning of a file gives unspecified behavior.

The alternate function <u>\_ungetwc\_r</u> is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The wide character pushed back, or WEOF on error.

#### **Portability**

C99

# 4.68 vfprintf, vprintf, vsprintf, vsnprintf, vasprintf, vasprintf—format argument list

#### **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
int vprintf(const char *fmt, va_list list);
int vfprintf(FILE *fp, const char *fmt, va_list list);
int vsprintf(char *str, const char *fmt, va_list list);
int vsnprintf(char *str, size_t size, const char *fmt,
   va_list list);
int vasprintf(char **strp, const char *fmt, va_list list);
char *vasnprintf(char *str, size_t *size, const char *fmt,
   va_list list);
int _vprintf_r(struct _reent *reent, const char *fmt,
   va_list list);
int _vfprintf_r(struct _reent *reent, FILE *fp,
   const char *fmt, va_list list);
int _vsprintf_r(struct _reent *reent, char *str,
   const char *fmt, va_list list);
int _vasprintf_r(struct _reent *reent, char **str,
   const char *fmt, va_list list);
int _vsnprintf_r(struct _reent *reent, char *str,
   size_t size, const char *fmt, va_list list);
char *_vasnprintf_r(struct _reent *reent, char *str,
   size_t *size, const char *fmt, va_list list);
```

#### Description

vprintf, vfprintf, vasprintf, vsprintf, vsnprintf, and vasnprintf are (respectively) variants of printf, fprintf, asprintf, sprintf, snprintf, and asnprintf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments. The caller is responsible for calling va\_end.

```
_vprintf_r, _vfprintf_r, _vasprintf_r, _vsprintf_r, _vsnprintf_r, and _vasnprintf_r are reentrant versions of the above.
```

#### Returns

The return values are consistent with the corresponding functions.

#### Portability

ANSI C requires vprintf, vfprintf, vsprintf, and vsnprintf. The remaining functions are newlib extensions.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 4.69 vfscanf, vsscanf—format argument list

## **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
int vscanf(const char *fmt, va_list list);
int vfscanf(FILE *fp, const char *fmt, va_list list);
int vsscanf(const char *str, const char *fmt, va_list list);
int _vscanf_r(struct _reent *reent, const char *fmt, va_list list);
int _vfscanf_r(struct _reent *reent, FILE *fp, const char *fmt, va_list list);
int _vsscanf_r(struct _reent *reent, const char *str, const char *fmt, va_list list);
```

#### Description

vscanf, vfscanf, and vsscanf are (respectively) variants of scanf, fscanf, and sscanf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments.

#### Returns

The return values are consistent with the corresponding functions: **vscanf** returns the number of input fields successfully scanned, converted, and stored; the return value does not include scanned fields which were not stored.

If vscanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

The routines \_vscanf\_r, \_vfscanf\_f, and \_vsscanf\_r are reentrant versions which take an additional first parameter which points to the reentrancy structure.

#### **Portability**

These are GNU extensions.

Supporting OS subroutines required:

# 4.70 vfwprintf, vwprintf, vswprintf—wide character format argument list

## **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
#include <wchar.h>
int vwprintf(const wchar_t *fmt, va_list list);
int vfwprintf(FILE *fp, const wchar_t *fmt, va_list list);
int vswprintf(wchar_t *str, size_t size, const wchar_t *fmt, va_list list);

int _vwprintf_r(struct _reent *reent, const wchar_t *fmt, va_list list);
int _vfwprintf_r(struct _reent *reent, FILE *fp, const wchar_t *fmt, va_list list);
int _vswprintf_r(struct _reent *reent, wchar_t *str, size_t size, const wchar_t *fmt, va_list list);
```

#### Description

vwprintf, vfwprintf and vswprintf are (respectively) variants of wprintf, fwprintf and swprintf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments. The caller is responsible for calling va\_end.

\_vwprintf\_r, \_vfwprintf\_r and \_vswprintf\_r are reentrant versions of the above.

#### Returns

The return values are consistent with the corresponding functions.

#### **Portability**

POSIX-1.2008 with extensions; C99 (compliant except for POSIX extensions). Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

#### See Also

wprintf, fwprintf and swprintf.

# 4.71 vfwscanf, vwscanf, vswscanf—scan and format argument list from wide character input

## **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
int vwscanf(const wchar_t *fmt, va_list list);
int vfwscanf(FILE *fp, const wchar_t *fmt, va_list list);
int vswscanf(const wchar_t *str, const wchar_t *fmt, va_list list);
int _vwscanf(struct _reent *reent, const wchar_t *fmt, va_list list);
int _vfwscanf(struct _reent *reent, FILE *fp, const wchar_t *fmt, va_list list);
int _vswscanf(struct _reent *reent, const wchar_t *str, const wchar_t *fmt, va_list list);
```

#### Description

vwscanf, vfwscanf, and vswscanf are (respectively) variants of wscanf, fwscanf, and swscanf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments.

#### Returns

The return values are consistent with the corresponding functions: vwscanf returns the number of input fields successfully scanned, converted, and stored; the return value does not include scanned fields which were not stored.

If vwscanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

The routines \_vwscanf, \_vfwscanf, and \_vswscanf are reentrant versions which take an additional first parameter which points to the reentrancy structure.

#### **Portability**

C99, POSIX-1.2008

# 4.72 viprintf, vfiprintf, vsiprintf, vsniprintf, vasiprintf, vasniprintf—format argument list (integer only)

#### **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
int viprintf(const char *fmt, va_list list);
int vfiprintf(FILE *fp, const char *fmt, va_list list);
int vsiprintf(char *str, const char *fmt, va_list list);
int vsniprintf(char *str, size_t size, const char *fmt,
   va_list list);
int vasiprintf(char **strp, const char *fmt, va_list list);
char *vasniprintf(char *str, size_t *size, const char *fmt,
   va_list list);
int _viprintf_r(struct _reent *reent, const char *fmt,
   va_list list);
int _vfiprintf_r(struct _reent *reent, FILE *fp,
   const char *fmt, va_list list);
int _vsiprintf_r(struct _reent *reent, char *str,
   const char *fmt, va_list list);
int _vsniprintf_r(struct _reent *reent, char *str,
   size_t size, const char *fmt, va_list list);
int _vasiprintf_r(struct _reent *reent, char **str,
   const char *fmt, va_list list);
char *_vasniprintf_r(struct _reent *reent, char *str,
   size_t *size, const char *fmt, va_list list);
```

#### Description

viprintf, vfiprintf, vasiprintf, vsiprintf, vsniprintf, and vasniprintf are (respectively) variants of iprintf, fiprintf, asiprintf, siprintf, sniprintf, and asniprintf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments. The caller is responsible for calling va\_end.

\_viprintf\_r, \_vfiprintf\_r, \_vasiprintf\_r, \_vsiprintf\_r, \_vsniprintf\_r, and \_vasniprintf\_r are reentrant versions of the above.

#### Returns

The return values are consistent with the corresponding functions:

#### **Portability**

All of these functions are newlib extensions.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 4.73 viscanf, vfiscanf, vsiscanf—format argument list

## **Synopsis**

```
#include <stdio.h>
#include <stdarg.h>
int viscanf(const char *fmt, va_list list);
int vfiscanf(FILE *fp, const char *fmt, va_list list);
int vsiscanf(const char *str, const char *fmt, va_list list);
int _viscanf_r(struct _reent *reent, const char *fmt, va_list list);
int _vfiscanf_r(struct _reent *reent, FILE *fp, const char *fmt, va_list list);
int _vsiscanf_r(struct _reent *reent, const char *str, const char *fmt, va_list list);
```

#### Description

viscanf, vfiscanf, and vsiscanf are (respectively) variants of iscanf, fiscanf, and siscanf. They differ only in allowing their caller to pass the variable argument list as a va\_list object (initialized by va\_start) rather than directly accepting a variable number of arguments.

#### Returns

The return values are consistent with the corresponding functions: viscanf returns the number of input fields successfully scanned, converted, and stored; the return value does not include scanned fields which were not stored.

If viscanf attempts to read at end-of-file, the return value is EOF.

If no fields were stored, the return value is 0.

The routines \_viscanf\_r, \_vfiscanf\_f, and \_vsiscanf\_r are reentrant versions which take an additional first parameter which points to the reentrancy structure.

#### **Portability**

These are newlib extensions.

Supporting OS subroutines required:

# 5 Strings and Memory ('string.h')

This chapter describes string-handling functions and functions for managing areas of memory. The corresponding declarations are in 'string.h'.

# 5.1 bcmp—compare two memory areas

## **Synopsis**

```
#include <strings.h>
int bcmp(const void *s1, const void *s2, size_t n);
```

## Description

This function compares not more than n bytes of the object pointed to by s1 with the object pointed to by s2.

This function is identical to memcmp.

#### Returns

The function returns an integer greater than, equal to or less than zero according to whether the object pointed to by s1 is greater than, equal to or less than the object pointed to by s2.

## Portability

bcmp requires no supporting OS subroutines.

# 5.2 bcopy—copy memory regions

# **Synopsis**

```
#include <strings.h>
void bcopy(const void *in, void *out, size_t n);
```

# Description

This function copies n bytes from the memory region pointed to by in to the memory region pointed to by out.

This function is implemented in term of memmove.

## Portability

bcopy requires no supporting OS subroutines.

# 5.3 bzero—initialize memory to zero

# **Synopsis**

```
#include <strings.h>
void bzero(void *b, size_t length);
```

## Description

bzero initializes length bytes of memory, starting at address b, to zero.

#### Returns

bzero does not return a result.

## Portability

bzero is in the Berkeley Software Distribution. Neither ANSI C nor the System V Interface Definition (Issue 2) require bzero.

bzero requires no supporting OS subroutines.

# 5.4 index—search for character in string

## **Synopsis**

```
#include <strings.h>
char * index(const char *string, int c);
```

## Description

This function finds the first occurrence of c (converted to a char) in the string pointed to by string (including the terminating null character).

This function is identical to strchr.

#### Returns

Returns a pointer to the located character, or a null pointer if c does not occur in string.

## Portability

index requires no supporting OS subroutines.

# 5.5 memccpy—copy memory regions with end-token check Synopsis

```
#include <string.h>
void* memccpy(void *restrict out, const void *restrict in,
   int endchar, size_t n);
```

## Description

This function copies up to n bytes from the memory region pointed to by in to the memory region pointed to by out. If a byte matching the endchar is encountered, the byte is copied and copying stops.

If the regions overlap, the behavior is undefined.

#### Returns

memccpy returns a pointer to the first byte following the endchar in the out region. If no byte matching endchar was copied, then NULL is returned.

#### **Portability**

memccpy is a GNU extension.

memccpy requires no supporting OS subroutines.

# 5.6 memchr—find character in memory

# Synopsis

```
#include <string.h>
void *memchr(const void *src, int c, size_t length);
```

## Description

This function searches memory starting at \*src for the character c. The search only ends with the first occurrence of c, or after length characters; in particular, NUL does not terminate the search.

#### Returns

If the character c is found within length characters of \*src, a pointer to the character is returned. If c is not found, then NULL is returned.

## **Portability**

memchr is ANSI C.

memchr requires no supporting OS subroutines.

# 5.7 memcmp—compare two memory areas

# Synopsis

```
#include <string.h>
int memcmp(const void *s1, const void *s2, size_t n);
```

# Description

This function compares not more than n characters of the object pointed to by s1 with the object pointed to by s2.

#### Returns

The function returns an integer greater than, equal to or less than zero according to whether the object pointed to by s1 is greater than, equal to or less than the object pointed to by s2.

# **Portability**

memcmp is ANSI C.

memcmp requires no supporting OS subroutines.

# 5.8 memcpy—copy memory regions

# **Synopsis**

# Description

This function copies n bytes from the memory region pointed to by in to the memory region pointed to by out.

If the regions overlap, the behavior is undefined.

### Returns

memcpy returns a pointer to the first byte of the out region.

## Portability

memcpy is ANSI C.

memcpy requires no supporting OS subroutines.

# 5.9 memmem—find memory segment

## **Synopsis**

## Description

Locates the first occurrence in the memory region pointed to by s1 with length l1 of the sequence of bytes pointed to by s2 of length l2. If you already know the lengths of your haystack and needle, memmem can be much faster than strstr.

#### Returns

Returns a pointer to the located segment, or a null pointer if s2 is not found. If l2 is 0, s1 is returned.

#### **Portability**

memmem is a newlib extension.

memmem requires no supporting OS subroutines.

# 5.10 memmove—move possibly overlapping memory

# **Synopsis**

```
#include <string.h>
void *memmove(void *dst, const void *src, size_t length);
```

## Description

This function moves length characters from the block of memory starting at \*src to the memory starting at \*dst. memmove reproduces the characters correctly at \*dst even if the two areas overlap.

#### Returns

The function returns dst as passed.

#### **Portability**

memmove is ANSI C.

memmove requires no supporting OS subroutines.

# 5.11 mempcpy—copy memory regions and return end pointer Synopsis

```
#include <string.h>
void* mempcpy(void *out, const void *in, size_t n);
```

## Description

This function copies n bytes from the memory region pointed to by in to the memory region pointed to by out.

If the regions overlap, the behavior is undefined.

#### Returns

mempcpy returns a pointer to the byte following the last byte copied to the out region.

## Portability

mempcpy is a GNU extension.

mempcpy requires no supporting OS subroutines.

# 5.12 memset—set an area of memory

# Synopsis

```
#include <string.h>
void *memset(void *dst, int c, size_t length);
```

# Description

This function converts the argument c into an unsigned char and fills the first length characters of the array pointed to by dst to the value.

#### Returns

memset returns the value of dst.

# Portability

memset is ANSI C.

memset requires no supporting OS subroutines.

# 5.13 rindex—reverse search for character in string

## **Synopsis**

```
#include <string.h>
char * rindex(const char *string, int c);
```

## Description

This function finds the last occurrence of c (converted to a char) in the string pointed to by string (including the terminating null character).

This function is identical to strrchr.

#### Returns

Returns a pointer to the located character, or a null pointer if c does not occur in string.

## Portability

rindex requires no supporting OS subroutines.

# 5.14 stpcpy—copy string returning a pointer to its end

# Synopsis

```
#include <string.h>
char *stpcpy(char *restrict dst, const char *restrict src);
```

## Description

stpcpy copies the string pointed to by src (including the terminating null character) to the array pointed to by dst.

#### Returns

This function returns a pointer to the end of the destination string, thus pointing to the trailing '\0'.

#### **Portability**

stpcpy is a GNU extension, candidate for inclusion into POSIX/SUSv4. stpcpy requires no supporting OS subroutines.

# 5.15 stpncpy—counted copy string returning a pointer to its end

# Synopsis

#### Description

stpncpy copies not more than length characters from the the string pointed to by src (including the terminating null character) to the array pointed to by dst. If the string pointed to by src is shorter than length characters, null characters are appended to the destination array until a total of length characters have been written.

#### Returns

This function returns a pointer to the end of the destination string, thus pointing to the trailing 0, or, if the destination string is not null-terminated, pointing to dst + n.

## **Portability**

stpncpy is a GNU extension, candidate for inclusion into POSIX/SUSv4. stpncpy requires no supporting OS subroutines.

# 5.16 strcasecmp—case-insensitive character string compare

# Synopsis

```
#include <strings.h>
int strcasecmp(const char *a, const char *b);
```

#### Description

strcasecmp compares the string at a to the string at b in a case-insensitive manner.

#### Returns

If \*a sorts lexicographically after \*b (after both are converted to lowercase), strcasecmp returns a number greater than zero. If the two strings match, strcasecmp returns zero. If \*a sorts lexicographically before \*b, strcasecmp returns a number less than zero.

#### Portability

strcasecmp is in the Berkeley Software Distribution.

strcasecmp requires no supporting OS subroutines. It uses to lower() from elsewhere in this library.

# 5.17 strcasestr—case-insensitive character string search

# Synopsis

```
#include <string.h>
char *strcasestr(const char *s, const char *find);
```

## Description

strcasestr searchs the string s for the first occurrence of the sequence find. strcasestr is identical to strstr except the search is case-insensitive.

#### Returns

A pointer to the first case-insensitive occurrence of the sequence find or NULL if no match was found.

## **Portability**

strcasestr is in the Berkeley Software Distribution.

strcasestr requires no supporting OS subroutines. It uses tolower() from elsewhere in this library.

# 5.18 strcat—concatenate strings

# Synopsis

```
#include <string.h>
char *strcat(char *restrict dst, const char *restrict src);
```

## Description

strcat appends a copy of the string pointed to by src (including the terminating null character) to the end of the string pointed to by dst. The initial character of src overwrites the null character at the end of dst.

#### Returns

This function returns the initial value of dst

## **Portability**

strcat is ANSI C.

strcat requires no supporting OS subroutines.

# 5.19 strchr—search for character in string

# Synopsis

```
#include <string.h>
char * strchr(const char *string, int c);
```

# Description

This function finds the first occurrence of c (converted to a char) in the string pointed to by string (including the terminating null character).

#### Returns

Returns a pointer to the located character, or a null pointer if c does not occur in string.

# Portability

strchr is ANSI C.

strchr requires no supporting OS subroutines.

# 5.20 strcmp—character string compare

# **Synopsis**

```
#include <string.h>
int strcmp(const char *a, const char *b);
```

## Description

strcmp compares the string at a to the string at b.

#### Returns

If \*a sorts lexicographically after \*b, strcmp returns a number greater than zero. If the two strings match, strcmp returns zero. If \*a sorts lexicographically before \*b, strcmp returns a number less than zero.

## **Portability**

strcmp is ANSI C.

strcmp requires no supporting OS subroutines.

# 5.21 strcoll—locale-specific character string compare

## **Synopsis**

```
#include <string.h>
int strcoll(const char *stra, const char * strb);
```

## Description

strcoll compares the string pointed to by stra to the string pointed to by strb, using an interpretation appropriate to the current LC\_COLLATE state.

#### Returns

If the first string is greater than the second string, strcoll returns a number greater than zero. If the two strings are equivalent, strcoll returns zero. If the first string is less than the second string, strcoll returns a number less than zero.

# Portability

strcoll is ANSI C.

strcoll requires no supporting OS subroutines.

# 5.22 strcpy—copy string

# Synopsis

```
#include <string.h>
char *strcpy(char *dst, const char *src);
```

# Description

 $\mathtt{strcpy}$  copies the string pointed to by src (including the terminating null character) to the array pointed to by dst.

#### Returns

This function returns the initial value of dst.

# Portability

strcpy is ANSI C.

strcpy requires no supporting OS subroutines.

# 5.23 strcspn—count characters not in string

# Synopsis

```
size_t strcspn(const char *s1, const char *s2);
```

## Description

This function computes the length of the initial part of the string pointed to by s1 which consists entirely of characters NOT from the string pointed to by s2 (excluding the terminating null character).

#### Returns

strcspn returns the length of the substring found.

# Portability

strcspn is ANSI C.

strcspn requires no supporting OS subroutines.

# 5.24 strerror—convert error number to string

#### **Synopsis**

```
#include <string.h>
char *strerror(int errnum);
char *_strerror_r(struct _reent ptr, int errnum,
    int internal, int *error);
```

## Description

strerror converts the error number errnum into a string. The value of errnum is usually a copy of errno. If errnum is not a known error number, the result points to an empty string. This implementation of strerror prints out the following strings for each of the values defined in 'errno.h':

0 Success

E2BIG Arg list too long

EACCES Permission denied

**EADDRINUSE** 

Address already in use

EADV Advertise error

**EAFNOSUPPORT** 

Address family not supported by protocol family

EAGAIN No more processes

EALREADY Socket already connected

EBADF Bad file number

EBADMSG Bad message

EBUSY Device or resource busy

ECHILD No children

ECOMM Communication error

**ECONNABORTED** 

Software caused connection abort

**ECONNREFUSED** 

Connection refused

EDEADLK Deadlock

**EDESTADDRREQ** 

Destination address required

EEXIST File exists

EDOM Math argument

EFAULT Bad address

EFBIG File too large

**EHOSTDOWN** 

Host is down

EHOSTUNREACH

Host is unreachable

EIDRM Identifier removed

**EINPROGRESS** 

Connection already in progress

EINTR Interrupted system call

EINVAL Invalid argument

EIO I/O error

EISCONN Socket is already connected

EISDIR Is a directory

ELIBACC Cannot access a needed shared library

ELIBBAD Accessing a corrupted shared library

ELIBEXEC Cannot exec a shared library directly

ELIBMAX Attempting to link in more shared libraries than system limit

ELIBSCN .lib section in a.out corrupted

EMFILE Too many open files

EMLINK Too many links

EMSGSIZE Message too long

**EMULTIHOP** 

Multihop attempted

ENAMETOOLONG

File or path name too long

ENETDOWN Network interface not configured

**ENETUNREACH** 

Network is unreachable

ENFILE Too many open files in system

**ENODEV** No such device

**ENOENT** No such file or directory

**ENOEXEC** Exec format error

ENOLCK No lock

**ENOLINK** Virtual circuit is gone

ENOMEM Not enough space

ENOMSG No message of desired type

**ENONET** Machine is not on the network

ENOPKG No package

**ENOPROTOOPT** 

Protocol not available

ENOSPC No space left on device

ENOSR No stream resources

ENOSTR Not a stream

**ENOSYS** Function not implemented

ENOTBLK Block device required

ENOTCONN Socket is not connected

**ENOTDIR** Not a directory

**ENOTEMPTY** 

Directory not empty

ENOTSOCK Socket operation on non-socket

ENOTSUP Not supported

**ENOTTY** Not a character device

ENXIO No such device or address

EPERM Not owner

EPIPE Broken pipe

EPROTO Protocol error

**EPROTOTYPE** 

Protocol wrong type for socket

**EPROTONOSUPPORT** 

Unknown protocol

ERANGE Result too large

EREMOTE Resource is remote

EROFS Read-only file system

**ESHUTDOWN** 

Can't send after socket shutdown

**ESOCKTNOSUPPORT** 

Socket type not supported

ESPIPE Illegal seek

ESRCH No such process

ESRMNT Srmount error

ETIME Stream ioctl timeout

ETIMEDOUT

Connection timed out

ETXTBSY Text file busy

EXDEV Cross-device link

**ECANCELED** 

Operation canceled

ENOTRECOVERABLE

State not recoverable

**EOWNERDEAD** 

Previous owner died

ESTRPIPE Strings pipe error

\_strerror\_r is a reentrant version of the above.

#### Returns

This function returns a pointer to a string. Your application must not modify that string.

#### Portability

ANSI C requires strerror, but does not specify the strings used for each error number.

Although this implementation of strerror is reentrant (depending on \_user\_strerror), ANSI C declares that subsequent calls to strerror may overwrite the result string; therefore portable code cannot depend on the reentrancy of this subroutine.

Although this implementation of strerror guarantees a non-null result with a NUL-terminator, some implementations return NULL on failure. Although POSIX allows strerror to set errno to EINVAL on failure, this implementation does not do so (unless you provide \_user\_strerror).

POSIX recommends that unknown *errnum* result in a message including that value, however it is not a requirement and this implementation does not provide that information (unless you provide \_user\_strerror).

This implementation of strerror provides for user-defined extensibility. errno.h defines \_\_ELASTERROR, which can be used as a base for user-defined error values. If the user supplies a routine named \_user\_strerror, and errnum passed to strerror does not match any of the supported values, \_user\_strerror is called with three arguments. The first is of type int, and is the errnum value unknown to strerror. The second is of type int, and matches the internal argument of \_strerror\_r; this should be zero if called from strerror and non-zero if called from any other function; \_user\_strerror can use this information to satisfy the POSIX rule that no other standardized function can overwrite a static buffer reused by strerror. The third is of type int \*, and matches the error argument of \_strerror\_r; if a non-zero value is stored into that location (usually EINVAL), then strerror will set errno to that value, and the XPG variant of strerror\_r will return that value instead of zero or ERANGE. \_user\_strerror returns a char \* value; returning

NULL implies that the user function did not choose to handle errnum. The default \_user\_strerror returns NULL for all input values. Note that \_user\_sterror must be thread-safe, and only denote errors via the third argument rather than modifying errno, if strerror and strerror\_r are are to comply with POSIX.

strerror requires no supporting OS subroutines.

# 5.25 strerror\_r—convert error number to string and copy to buffer

## **Synopsis**

```
#include <string.h>
#ifdef _GNU_SOURCE
char *strerror_r(int errnum, char *buffer, size_t n);
#else
int strerror_r(int errnum, char *buffer, size_t n);
#endif
```

#### Description

strerror\_r converts the error number errnum into a string and copies the result into the supplied buffer for a length up to n, including the NUL terminator. The value of errnum is usually a copy of errno. If errnum is not a known error number, the result is the empty string.

See strerror for how strings are mapped to errnum.

#### Returns

There are two variants: the GNU version always returns a NUL-terminated string, which is buffer if all went well, but which is another pointer if n was too small (leaving buffer untouched). If the return is not buffer, your application must not modify that string. The POSIX version returns 0 on success, EINVAL if errnum was not recognized, and ERANGE if n was too small. The variant chosen depends on macros that you define before inclusion of string.h.

#### Portability

strerror\_r with a char \* result is a GNU extension. strerror\_r with an int result is required by POSIX 2001. This function is compliant only if \_user\_strerror is not provided, or if it is thread-safe and uses separate storage according to whether the second argument of that function is non-zero. For more details on \_user\_strerror, see the strerror documentation.

POSIX states that the contents of buf are unspecified on error, although this implementation guarantees a NUL-terminated string for all except n of 0.

POSIX recommends that unknown errnum result in a message including that value, however it is not a requirement and this implementation provides only an empty string (unless you provide \_user\_strerror). POSIX also recommends that unknown errnum fail with EINVAL even when providing such a message, however it is not a requirement and this implementation will return success if \_user\_strerror provided a non-empty alternate string without assigning into its third argument.

strerror\_r requires no supporting OS subroutines.

# 5.26 strlen—character string length

# Synopsis

```
#include <string.h>
size_t strlen(const char *str);
```

## Description

The strlen function works out the length of the string starting at \*str by counting characters until it reaches a NULL character.

#### Returns

strlen returns the character count.

# Portability

strlen is ANSI C.

strlen requires no supporting OS subroutines.

# 5.27 strlwr—force string to lowercase

# **Synopsis**

```
#include <string.h>
char *strlwr(char *a);
```

# Description

strlwr converts each character in the string at a to lowercase.

#### Returns

 ${\tt strlwr}$  returns its argument, a.

# Portability

strlwr is not widely portable.

strlwr requires no supporting OS subroutines.

# 5.28 strncasecmp—case-insensitive character string compare Synopsis

```
#include <strings.h>
int strncasecmp(const char *a, const char * b, size_t length);
```

#### Description

**strncasecmp** compares up to *length* characters from the string at a to the string at b in a case-insensitive manner.

#### Returns

If \*a sorts lexicographically after \*b (after both are converted to lowercase), strncasecmp returns a number greater than zero. If the two strings are equivalent, strncasecmp returns zero. If \*a sorts lexicographically before \*b, strncasecmp returns a number less than zero.

#### **Portability**

strncasecmp is in the Berkeley Software Distribution.

strncasecmp requires no supporting OS subroutines. It uses tolower() from elsewhere in this library.

# 5.29 strncat—concatenate strings

## **Synopsis**

## Description

strncat appends not more than length characters from the string pointed to by src (including the terminating null character) to the end of the string pointed to by dst. The initial character of src overwrites the null character at the end of dst. A terminating null character is always appended to the result

#### Warnings

Note that a null is always appended, so that if the copy is limited by the length argument, the number of characters appended to dst is n + 1.

#### Returns

This function returns the initial value of dst

#### **Portability**

strncat is ANSI C.

strncat requires no supporting OS subroutines.

# 5.30 strncmp—character string compare

# **Synopsis**

```
#include <string.h>
int strncmp(const char *a, const char * b, size_t length);
```

## Description

strncmp compares up to length characters from the string at a to the string at b.

#### Returns

If \*a sorts lexicographically after \*b, strncmp returns a number greater than zero. If the two strings are equivalent, strncmp returns zero. If \*a sorts lexicographically before \*b, strncmp returns a number less than zero.

#### **Portability**

strncmp is ANSI C.

strncmp requires no supporting OS subroutines.

# 5.31 strncpy—counted copy string

## **Synopsis**

## Description

strncpy copies not more than *length* characters from the the string pointed to by *src* (including the terminating null character) to the array pointed to by *dst*. If the string pointed to by *src* is shorter than *length* characters, null characters are appended to the destination array until a total of *length* characters have been written.

#### Returns

This function returns the initial value of dst.

## **Portability**

strncpy is ANSI C.

strncpy requires no supporting OS subroutines.

# 5.32 strnlen—character string length

# **Synopsis**

```
#include <string.h>
size_t strnlen(const char *str, size_t n);
```

## Description

The strnlen function works out the length of the string starting at \*str by counting characters until it reaches a NUL character or the maximum: n number of characters have been inspected.

#### Returns

strnlen returns the character count or n.

#### **Portability**

strnlen is a GNU extension.

strnlen requires no supporting OS subroutines.

# 5.33 strpbrk—find characters in string

# **Synopsis**

```
#include <string.h>
char *strpbrk(const char *s1, const char *s2);
```

# Description

This function locates the first occurrence in the string pointed to by s1 of any character in string pointed to by s2 (excluding the terminating null character).

#### Returns

strpbrk returns a pointer to the character found in s1, or a null pointer if no character from s2 occurs in s1.

# Portability

strpbrk requires no supporting OS subroutines.

# 5.34 strrchr—reverse search for character in string

# Synopsis

```
#include <string.h>
char * strrchr(const char *string, int c);
```

# Description

This function finds the last occurrence of c (converted to a char) in the string pointed to by string (including the terminating null character).

#### Returns

Returns a pointer to the located character, or a null pointer if c does not occur in string.

# Portability

strrchr is ANSI C.

strrchr requires no supporting OS subroutines.

# 5.35 strsignal—convert signal number to string

# **Synopsis**

```
#include <string.h>
char *strsignal(int signal);
```

## Description

strsignal converts the signal number signal into a string. If signal is not a known signal number, the result will be of the form "Unknown signal NN" where NN is the signal is a decimal number.

#### Returns

This function returns a pointer to a string. Your application must not modify that string.

#### **Portability**

POSIX.1-2008 C requires strsignal, but does not specify the strings used for each signal number.

strsignal requires no supporting OS subroutines.

# 5.36 strspn—find initial match

# **Synopsis**

```
#include <string.h>
size_t strspn(const char *s1, const char *s2);
```

## Description

This function computes the length of the initial segment of the string pointed to by s1 which consists entirely of characters from the string pointed to by s2 (excluding the terminating null character).

#### Returns

strspn returns the length of the segment found.

# Portability

strspn is ANSI C.

strspn requires no supporting OS subroutines.

# 5.37 strstr—find string segment

# **Synopsis**

```
#include <string.h>
char *strstr(const char *s1, const char *s2);
```

## Description

Locates the first occurrence in the string pointed to by s1 of the sequence of characters in the string pointed to by s2 (excluding the terminating null character).

#### Returns

Returns a pointer to the located string segment, or a null pointer if the string s2 is not found. If s2 points to a string with zero length, s1 is returned.

#### **Portability**

strstr is ANSI C.

strstr requires no supporting OS subroutines.

# 5.38 strtok, strtok\_r, strsep—get next token from a string Synopsis

#### Description

The strtok function is used to isolate sequential tokens in a null-terminated string, \*source. These tokens are delimited in the string by at least one of the characters in \*delimiters. The first time that strtok is called, \*source should be specified; subsequent calls, wishing to obtain further tokens from the same string, should pass a null pointer instead. The separator string, \*delimiters, must be supplied each time and may change between calls.

The strtok function returns a pointer to the beginning of each subsequent token in the string, after replacing the separator character itself with a null character. When no more tokens remain, a null pointer is returned.

The strtok\_r function has the same behavior as strtok, except a pointer to placeholder \*lasts must be supplied by the caller.

The strsep function is similar in behavior to strtok, except a pointer to the string pointer must be supplied <code>source\_ptr</code> and the function does not skip leading delimiters. When the string starts with a delimiter, the delimiter is changed to the null character and the empty string is returned. Like <code>strtok\_r</code> and <code>strtok</code>, the <code>\*source\_ptr</code> is updated to the next character following the last delimiter found or NULL if the end of string is reached with no more delimiters.

#### Returns

strtok, strtok\_r, and strsep all return a pointer to the next token, or NULL if no more tokens can be found. For strsep, a token may be the empty string.

#### **Portability**

```
strtok is ANSI C. strtok_r is POSIX. strsep is a BSD extension. strtok, strtok_r, and strsep require no supporting OS subroutines.
```

# 5.39 strupr—force string to uppercase

# **Synopsis**

```
#include <string.h>
char *strupr(char *a);
```

# Description

strupr converts each character in the string at a to uppercase.

#### Returns

strupr returns its argument, a.

# Portability

 ${\tt strupr}$  is not widely portable.

strupr requires no supporting OS subroutines.

# 5.40 strxfrm—transform string

#### **Synopsis**

#### Description

This function transforms the string pointed to by s2 and places the resulting string into the array pointed to by s1. The transformation is such that if the **strcmp** function is applied to the two transformed strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of a **strcoll** function applied to the same two original strings.

No more than n characters are placed into the resulting array pointed to by s1, including the terminating null character. If n is zero, s1 may be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

With a C locale, this function just copies.

#### Returns

The strxfrm function returns the length of the transformed string (not including the terminating null character). If the value returned is n or more, the contents of the array pointed to by s1 are indeterminate.

#### Portability

strxfrm is ANSI C.

strxfrm requires no supporting OS subroutines.

# 5.41 swab—swap adjacent bytes

# **Synopsis**

```
#include <unistd.h>
void swab(const void *in, void *out, ssize_t n);
```

# Description

This function copies n bytes from the memory region pointed to by in to the memory region pointed to by out, exchanging adjacent even and odd bytes.

# Portability

swab requires no supporting OS subroutines.

# 5.42 wcscasecmp—case-insensitive wide character string compare

# **Synopsis**

```
#include <wchar.h>
int wcscasecmp(const wchar_t *a, const wchar_t *b);
```

## Description

wcscasecmp compares the wide character string at a to the wide character string at b in a case-insensitive manner.

#### Returns

If \*a sorts lexicographically after \*b (after both are converted to uppercase), wcscasecmp returns a number greater than zero. If the two strings match, wcscasecmp returns zero. If \*a sorts lexicographically before \*b, wcscasecmp returns a number less than zero.

# Portability

POSIX-1.2008

wcscasecmp requires no supporting OS subroutines. It uses tolower() from elsewhere in this library.

# 5.43 wcsdup—wide character string duplicate

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcsdup(const wchar_t *str);

#include <wchar.h>
wchar_t *_wcsdup_r(struct _reent *ptr, const wchar_t *str);
```

## Description

wcsdup allocates a new wide character string using malloc, and copies the content of the argument str into the newly allocated string, thus making a copy of str.

#### Returns

wcsdup returns a pointer to the copy of str if enough memory for the copy was available. Otherwise it returns NULL and errno is set to ENOMEM.

#### **Portability**

POSIX-1.2008

# 5.44 wcsncasecmp—case-insensitive wide character string compare

# **Synopsis**

```
#include <wchar.h>
int wcsncasecmp(const wchar_t *a, const wchar_t * b, size_t length);
```

## Description

wcsncasecmp compares up to *length* wide characters from the string at a to the string at b in a case-insensitive manner.

#### Returns

If \*a sorts lexicographically after \*b (after both are converted to uppercase), wcsncasecmp returns a number greater than zero. If the two strings are equivalent, wcsncasecmp returns zero. If \*a sorts lexicographically before \*b, wcsncasecmp returns a number less than zero.

# Portability

POSIX-1.2008

wcsncasecmp requires no supporting OS subroutines. It uses tolower() from elsewhere in this library.

# 6 Wide Character Strings ('wchar.h')

This chapter describes wide-character string-handling functions and managing areas of memory containing wide characters. The corresponding declarations are in 'wchar.h'.

# 6.1 wmemchr—find a wide character in memory

## **Synopsis**

```
#include <wchar.h>
wchar_t *wmemchr(const wchar_t *s, wchar_t c, size_t n);
```

#### Description

The wmemchr function locates the first occurrence of c in the initial n wide characters of the object pointed to be s. This function is not affected by locale and all wchar\_t values are treated identically. The null wide character and wchar\_t values not corresponding to valid characters are not treated specially.

If n is zero, s must be a valid pointer and the function behaves as if no valid occurrence of c is found.

#### Returns

The wmemchr function returns a pointer to the located wide character, or a null pointer if the wide character does not occur in the object.

#### **Portability**

wmemchr is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.2 wmemcmp—compare wide characters in memory

## **Synopsis**

```
#include <wchar.h>
int wmemcmp(const wchar_t *s1, const wchar_t *s2, size_t n);
```

#### Description

The wmemcmp function compares the first n wide characters of the object pointed to by s1 to the first n wide characters of the object pointed to by s2. This function is not affected by locale and all wchar\_t values are treated identically. The null wide character and wchar\_t values not corresponding to valid characters are not treated specially.

If n is zero, s1 and s2 must be a valid pointers and the function behaves as if the two objects compare equal.

#### Returns

The wmemcmp function returns an integer greater than, equal to, or less than zero, accordingly as the object pointed to by s1 is greater than, equal to, or less than the object pointed to by s2.

#### **Portability**

wmemcmp is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.3 wmemcpy—copy wide characters in memory

## **Synopsis**

```
#include <wchar.h>
wchar_t *wmemcpy(wchar_t *d, const wchar_t *s, size_t n);
```

## Description

The wmemcpy function copies n wide characters from the object pointed to by s to the object pointed to be d. This function is not affected by locale and all wchar\_t values are treated identically. The null wide character and wchar\_t values not corresponding to valid characters are not treated specially.

If n is zero, d and s must be a valid pointers, and the function copies zero wide characters.

#### Returns

The wmemcpy function returns the value of d.

# Portability

wmemcpy is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.4 wmemmove—copy wide characters in memory with overlapping areas

#### **Synopsis**

```
#include <wchar.h>
wchar_t *wmemmove(wchar_t *d, const wchar_t *s, size_t n);
```

#### Description

The wmemmove function copies n wide characters from the object pointed to by s to the object pointed to by d. Copying takes place as if the n wide characters from the object pointed to by s are first copied into a temporary array of s wide characters that does not overlap the objects pointed to by s and then the s wide characters from the temporary array are copied into the object pointed to by s.

This function is not affected by locale and all wchar\_t values are treated identically. The null wide character and wchar\_t values not corresponding to valid characters are not treated specially.

If n is zero, d and s must be a valid pointers, and the function copies zero wide characters.

#### Returns

The wmemmove function returns the value of d.

#### **Portability**

wmemmove is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.5 wmemset—set wide characters in memory

## Synopsis

```
#include <wchar.h>
wchar_t *wmemset(wchar_t *s, wchar_t c, size_t n);
```

#### Description

The wmemset function copies the value of c into each of the first n wide characters of the object pointed to by s. This function is not affected by locale and all wchar\_t values are treated identically. The null wide character and wchar\_t values not corresponding to valid characters are not treated specially.

If n is zero, s must be a valid pointer and the function copies zero wide characters.

#### Returns

The wmemset function returns the value of s.

## Portability

wmemset is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.6 wcscat—concatenate two wide-character strings

## **Synopsis**

```
#include <wchar.h>
wchar_t *wcscat(wchar_t *s1, const wchar_t *s2);
```

#### Description

The wcscat function appends a copy of the wide-character string pointed to by s2 (including the terminating null wide-character code) to the end of the wide-character string pointed to by s1. The initial wide-character code of s2 overwrites the null wide-character code at the end of s1. If copying takes place between objects that overlap, the behaviour is undefined.

#### Returns

The wcscat function returns s1; no return value is reserved to indicate an error.

#### **Portability**

wcscat is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.7 wcschr—wide-character string scanning operation

## **Synopsis**

```
#include <wchar.h>
wchar_t *wcschr(const wchar_t *s, wchar_t c);
```

#### Description

The wcschr function locates the first occurrence of c in the wide-character string pointed to by s. The value of c must be a character representable as a type wchar\_t and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character string.

#### Returns

Upon completion, wcschr returns a pointer to the wide-character code, or a null pointer if the wide-character code is not found.

#### **Portability**

wcschr is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.8 wcscmp—compare two wide-character strings

# Synopsis

```
#include <wchar.h>
int wcscmp(const wchar_t *s1, *s2);
```

#### Description

The wcscmp function compares the wide-character string pointed to by s1 to the wide-character string pointed to by s2.

The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared.

#### Returns

Upon completion, wcscmp returns an integer greater than, equal to or less than 0, if the wide-character string pointed to by s1 is greater than, equal to or less than the wide-character string pointed to by s2 respectively.

#### **Portability**

wcscmp is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.9 wcscoll—locale-specific wide-character string compare Synopsis

```
#include <wchar.h>
int wcscoll(const wchar_t *stra, const wchar_t * strb);
```

#### Description

wcscoll compares the wide-character string pointed to by stra to the wide-character string pointed to by strb, using an interpretation appropriate to the current  $LC\_COLLATE$  state.

The current implementation of wcscoll simply uses wcscmp and does not support any language-specific sorting.

#### Returns

If the first string is greater than the second string, wcscoll returns a number greater than zero. If the two strings are equivalent, wcscoll returns zero. If the first string is less than the second string, wcscoll returns a number less than zero.

#### **Portability**

wcscoll is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.10 wcscpy—copy a wide-character string

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcscpy(wchar_t *s1, const wchar_t *,s2);
```

## Description

The wcscpy function copies the wide-character string pointed to by s2 (including the terminating null wide-character code) into the array pointed to by s1. If copying takes place between objects that overlap, the behaviour is undefined.

#### Returns

The wcscpy function returns s1; no return value is reserved to indicate an error.

#### **Portability**

wcscpy is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.11 wcpcpy—copy a wide-character string returning a pointer to its end

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcpcpy(wchar_t *s1, const wchar_t *,s2);
```

## Description

The wcpcpy function copies the wide-character string pointed to by s2 (including the terminating null wide-character code) into the array pointed to by s1. If copying takes place between objects that overlap, the behaviour is undefined.

#### Returns

This function returns a pointer to the end of the destination string, thus pointing to the trailing '\0'.

# Portability

wcpcpy is a GNU extension.

# 6.12 wcscspn—get length of a complementary wide substring Synopsis

```
#include <wchar.h>
size_t wcscspn(const wchar_t *s, wchar_t *set);
```

## Description

The wcscspn function computes the length of the maximum initial segment of the wide-character string pointed to by s which consists entirely of wide-character codes not from the wide-character string pointed to by set.

#### Returns

The wcscspn function returns the length of the initial substring of s1; no return value is reserved to indicate an error.

# Portability

wcscspn is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.13 wcsftime-convert date and time to a formatted widecharacter string

### **Synopsis**

#### Description

wcsftime is equivalent to strftime, except that:

- The argument s points to the initial element of an array of wide characters into which the generated output is to be placed.
- The argument maxsize indicates the limiting number of wide characters.
- The argument format is a wide-character string and the conversion specifiers are replaced by corresponding sequences of wide characters.
- The return value indicates the number of wide characters.

(The difference in all of the above being wide characters versus regular characters.) See strftime for the details of the format specifiers.

#### Returns

When the formatted time takes up no more than maxsize wide characters, the result is the length of the formatted wide string. Otherwise, if the formatting operation was abandoned due to lack of room, the result is 0, and the wide-character string starting at s corresponds to just those parts of \*format\* that could be completely filled in within the maxsize limit.

#### **Portability**

C99 and POSIX require wcsftime, but do not specify the contents of \*s when the formatted string would require more than maxsize characters. Unrecognized specifiers and fields of timp that are out of range cause undefined results. Since some formats expand to 0 bytes, it is wise to set \*s to a nonzero value beforehand to distinguish between failure and an empty string. This implementation does not support s being NULL, nor overlapping s and format.

wcsftime requires no supporting OS subroutines.

#### See Also

strftime

# 6.14 wcslcat—concatenate wide-character strings to specified length

# **Synopsis**

```
#include <wchar.h>
size_t wcslcat(wchar_t *dst, const wchar_t *src, size_t siz);
```

#### Description

The wcslcat function appends wide characters from src to end of the dst wide-character string so that the resultant wide-character string is not more than siz wide characters including the terminating null wide-character code. A terminating null wide character is always added unless siz is 0. Thus, the maximum number of wide characters that can be appended from src is siz - 1. If copying takes place between objects that overlap, the behaviour is undefined.

#### Returns

Wide-character string length of initial dst plus the wide-character string length of src (does not include terminating null wide-characters). If the return value is greater than or equal to siz, then truncation occurred and not all wide characters from src were appended.

#### **Portability**

# 6.15 wcslcpy—copy a wide-character string to specified length

# **Synopsis**

```
#include <wchar.h>
size_t wcslcpy(wchar_t *dst, const wchar_t *src, size_t siz);
```

## Description

wcslcpy copies wide characters from src to dst such that up to siz - 1 characters are copied. A terminating null is appended to the result, unless siz is zero.

#### Returns

wcslcpy returns the number of wide characters in src, not including the terminating null wide character. If the return value is greater than or equal to siz, then not all wide characters were copied from src and truncation occurred.

# Portability

# 6.16 wcslen—get wide-character string length

# **Synopsis**

```
#include <wchar.h>
size_t wcslen(const wchar_t *s);
```

## Description

The wcslen function computes the number of wide-character codes in the wide-character string to which s points, not including the terminating null wide-character code.

#### Returns

The wcslen function returns the length of s; no return value is reserved to indicate an error.

# Portability

wcslen is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.17 wcsncat—concatenate part of two wide-character strings

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcsncat(wchar_t *s1, const wchar_t *s2, size_t n);
```

#### Description

The wcsncat function appends not more than n wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by s2 to the end of the wide-character string pointed to by s1. The initial wide-character code of s2 overwrites the null wide-character code at the end of s1. A terminating null wide-character code is always appended to the result. If copying takes place between objects that overlap, the behaviour is undefined.

#### Returns

The wcsncat function returns s1; no return value is reserved to indicate an error.

#### **Portability**

wcsncat is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.18 wcsncmp—compare part of two wide-character strings Synopsis

```
#include <wchar.h>
int wcsncmp(const wchar_t *s1, const wchar_t *s2, size_t n);
```

### Description

The wcsncmp function compares not more than n wide-character codes (wide-character codes that follow a null wide-character code are not compared) from the array pointed to by s1 to the array pointed to by s2.

The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared.

#### Returns

Upon successful completion, wcsncmp returns an integer greater than, equal to or less than 0, if the possibly null-terminated array pointed to by s1 is greater than, equal to or less than the possibly null-terminated array pointed to by s2 respectively.

#### Portability

wcsncmp is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.19 wcsncpy—copy part of a wide-character string

# Synopsis

```
#include <wchar.h>
wchar_t *wcsncpy(wchar_t *s1, const wchar_t *s2, size_t n);
```

### Description

The wcsncpy function copies not more than n wide-character codes (wide-character codes that follow a null wide-character code are not copied) from the array pointed to by s2 to the array pointed to by s1. If copying takes place between objects that overlap, the behaviour is undefined. Note that if s1 contains more than n wide characters before its terminating null, the result is not null-terminated.

If the array pointed to by s2 is a wide-character string that is shorter than n wide-character codes, null wide-character codes are appended to the copy in the array pointed to by s1, until n wide-character codes in all are written.

#### Returns

The wcsncpy function returns s1; no return value is reserved to indicate an error.

### **Portability**

ISO/IEC 9899; POSIX.1.

# 6.20 wcpncpy—copy part of a wide-character string returning a pointer to its end

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcpncpy(wchar_t *s1, const wchar_t *s2, size_t n);
```

#### Description

The wcpncpy function copies not more than n wide-character codes (wide-character codes that follow a null wide-character code are not copied) from the array pointed to by s2 to the array pointed to by s1. If copying takes place between objects that overlap, the behaviour is undefined.

If the array pointed to by s2 is a wide-character string that is shorter than n wide-character codes, null wide-character codes are appended to the copy in the array pointed to by s1, until n wide-character codes in all are written.

#### Returns

The wcpncpy function returns s1; no return value is reserved to indicate an error.

#### **Portability**

wcpncpy is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.21 wcsnlen—get fixed-size wide-character string length

# **Synopsis**

```
#include <wchar.h>
size_t wcsnlen(const wchar_t *s, size_t maxlen);
```

## Description

The wcsnlen function computes the number of wide-character codes in the wide-character string pointed to by s not including the terminating L'\0' wide character but at most maxlen wide characters.

#### Returns

wcsnlen returns the length of s if it is less than maxlen, or maxlen if there is no L'\0' wide character in first maxlen characters.

#### **Portability**

wcsnlen is a GNU extension.

wcsnlen requires no supporting OS subroutines.

# 6.22 wcspbrk—-scan wide-character string for a wide-character code

# **Synopsis**

```
#include <wchar.h>
wchar_t *wcspbrk(const wchar_t *s, const wchar_t *set);
```

## Description

The wcspbrk function locates the first occurrence in the wide-character string pointed to by s of any wide-character code from the wide-character string pointed to by set.

#### Returns

Upon successful completion, wcspbrk returns a pointer to the wide-character code or a null pointer if no wide-character code from set occurs in s.

## Portability

wcspbrk is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.23 wcsrchr—wide-character string scanning operation

# Synopsis

```
#include <wchar.h>
wchar_t *wcsrchr(const wchar_t *s, wchar_t c);
```

#### Description

The wcsrchr function locates the last occurrence of c in the wide-character string pointed to by s. The value of c must be a character representable as a type wchar\_t and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string.

#### Returns

Upon successful completion, wcsrchr returns a pointer to the wide-character code or a null pointer if c does not occur in the wide-character string.

#### **Portability**

wcsrchr is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.24 wcsspn—get length of a wide substring

# **Synopsis**

```
#include <wchar.h>
size_t wcsspn(const wchar_t *s, const wchar_t *set);
```

## Description

The wcsspn function computes the length of the maximum initial segment of the wide-character string pointed to by s which consists entirely of wide-character codes from the wide-character string pointed to by set.

#### Returns

The wcsspn() function returns the length s1; no return value is reserved to indicate an error.

# Portability

wcsspn is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.25 wcsstr—find a wide-character substring

### **Synopsis**

```
#include <wchar.h>
wchar_t *wcsstr(const wchar_t *big, const wchar_t *little);
```

#### Description

The wcsstr function locates the first occurrence in the wide-character string pointed to by big of the sequence of wide characters (excluding the terminating null wide character) in the wide-character string pointed to by little.

#### Returns

On successful completion, wcsstr returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found.

If little points to a wide-character string with zero length, the function returns big.

## Portability

wcsstr is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.26 wcstok—get next token from a string

### **Synopsis**

#### Description

The wcstok function is the wide-character equivalent of the strtok\_r function (which in turn is the same as the strtok function with an added argument to make it thread-safe).

The wcstok function is used to isolate (one at a time) sequential tokens in a null-terminated wide-character string, \*source. A token is defined as a substring not containing any wide-characters from \*delimiters.

The first time that wcstok is called, \*source should be specified with the wide-character string to be searched, and \*lasts-but not lasts, which must be non-NULL-may be random; subsequent calls, wishing to obtain further tokens from the same string, should pass a null pointer for \*source instead but must supply \*lasts unchanged from the last call. The separator wide-character string, \*delimiters, must be supplied each time and may change between calls. A pointer to placeholder \*lasts must be supplied by the caller, and is set each time as needed to save the state by wcstok. Every call to wcstok with \*source == NULL must pass the value of \*lasts as last set by wcstok.

The wcstok function returns a pointer to the beginning of each subsequent token in the string, after replacing the separator wide-character itself with a null wide-character. When no more tokens remain, a null pointer is returned.

#### Returns

wcstok returns a pointer to the first wide character of a token, or NULL if there is no token.

#### **Portability**

wcstok is C99 and POSIX.1-2001.

wcstok requires no supporting OS subroutines.

# 6.27 wcswidth—number of column positions of a widecharacter string

# **Synopsis**

```
#include <wchar.h>
int wcswidth(const wchar_t *pwcs, size_t n);
```

#### Description

The wcswidth function shall determine the number of column positions required for n wide-character codes (or fewer than n wide-character codes if a null wide-character code is encountered before n wide-character codes are exhausted) in the string pointed to by pwcs.

#### Returns

The wcswidth function either shall return 0 (if pwcs points to a null wide-character code), or return the number of column positions to be occupied by the wide-character string pointed to by pwcs, or return -1 (if any of the first n wide-character codes in the wide-character string pointed to by pwcs is not a printable wide-character code).

# Portability

wcswidth has been introduced in the Single UNIX Specification Volume 2. wcswidth has been marked as an extension in the Single UNIX Specification Volume 3.

# 6.28 wcsxfrm—locale-specific wide-character string transformation

# **Synopsis**

```
#include <wchar.h>
int wcsxfrm(wchar_t *stra, const wchar_t * strb, size_t n);
```

#### Description

wcsxfrm transforms the wide-character string pointed to by strb to the wide-character string pointed to by stra, Comparing two transformed wide strings with wcscmp should return the same result as comparing the original strings with wcscoll. No more than n wide characters are transformed, including the trailing null character.

If n is 0, stra may be a NULL pointer.

The current implementation of wcsxfrm simply uses wcslcpy and does not support any language-specific transformations.

#### Returns

wcsxfrm returns the length of the transformed wide character string. if the return value is greater or equal to n, the content of stra is undefined.

### **Portability**

wcsxfrm is ISO/IEC 9899/AMD1:1995 (ISO C).

# 6.29 wcwidth—number of column positions of a wide-character code

# **Synopsis**

```
#include <wchar.h>
int wcwidth(const wchar_t wc);
```

#### Description

The wcwidth function shall determine the number of column positions required for the wide character wc. The application shall ensure that the value of wc is a character representable as a wchar\_t, and is a wide-character code corresponding to a valid character in the current locale.

#### Returns

The wcwidth function shall either return 0 (if wc is a null wide-character code), or return the number of column positions to be occupied by the wide-character code wc, or return -1 (if wc does not correspond to a printable wide-character code).

#### **Portability**

wcwidth has been introduced in the Single UNIX Specification Volume 2. wcwidth has been marked as an extension in the Single UNIX Specification Volume 3.

# 7 Signal Handling ('signal.h')

A signal is an event that interrupts the normal flow of control in your program. Your operating environment normally defines the full set of signals available (see 'sys/signal.h'), as well as the default means of dealing with them—typically, either printing an error message and aborting your program, or ignoring the signal.

All systems support at least the following signals:

SIGABRT Abnormal termination of a program; raised by the <<abort>> function.

SIGFPE A domain error in arithmetic, such as overflow, or division by zero.

SIGILL Attempt to execute as a function data that is not executable.

SIGINT Interrupt; an interactive attention signal.

SIGSEGV An attempt to access a memory location that is not available.

SIGTERM A request that your program end execution.

Two functions are available for dealing with asynchronous signals—one to allow your program to send signals to itself (this is called *raising* a signal), and one to specify subroutines (called *handlers* to handle particular signals that you anticipate may occur—whether raised by your own program or the operating environment.

To support these functions, 'signal.h' defines three macros:

- SIG\_DFL Used with the signal function in place of a pointer to a handler subroutine, to select the operating environment's default handling of a signal.
- SIG\_IGN Used with the signal function in place of a pointer to a handler, to ignore a particular signal.
- SIG\_ERR Returned by the signal function in place of a pointer to a handler, to indicate that your request to set up a handler could not be honored for some reason.

'signal.h' also defines an integral type, sig\_atomic\_t. This type is not used in any function declarations; it exists only to allow your signal handlers to declare a static storage location where they may store a signal value. (Static storage is not otherwise reliable from signal handlers.)

# 7.1 psignal—print a signal message on standard error

# Synopsis

```
#include <stdio.h>
void psignal(int signal, const char *prefix);
```

## Description

Use psignal to print (on standard error) a signal message corresponding to the value of the signal number signal. Unless you use NULL as the value of the argument prefix, the signal message will begin with the string at prefix, followed by a colon and a space (:). The remainder of the signal message is one of the strings described for strsignal.

#### Returns

psignal returns no result.

# Portability

POSIX.1-2008 requires psignal, but the strings issued vary from one implementation to another.

Supporting OS subroutines required: close, fstat, isatty, lseek, read, sbrk, write.

# 7.2 raise—send a signal

## **Synopsis**

```
#include <signal.h>
int raise(int sig);
int _raise_r(void *reent, int sig);
```

# Description

Send the signal sig (one of the macros from 'sys/signal.h'). This interrupts your program's normal flow of execution, and allows a signal handler (if you've defined one, using signal) to take control.

The alternate function <code>\_raise\_r</code> is a reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

The result is 0 if sig was successfully raised, 1 otherwise. However, the return value (since it depends on the normal flow of execution) may not be visible, unless the signal handler for sig terminates with a return or unless SIG\_IGN is in effect for this signal.

#### Portability

ANSI C requires raise, but allows the full set of signal numbers to vary from one implementation to another.

Required OS subroutines: getpid, kill.

# 7.3 signal—specify handler subroutine for a signal

# **Synopsis**

```
#include <signal.h>
void (*signal(int sig, void(*func)(int))) (int);

void (*_signal_r(void *reent, int sig, void(*func)(int))) (int);
```

#### Description

signal provides a simple signal-handling implementation for embedded targets.

signal allows you to request changed treatment for a particular signal sig. You can use one of the predefined macros SIG\_DFL (select system default handling) or SIG\_IGN (ignore this signal) as the value of func; otherwise, func is a function pointer that identifies a subroutine in your program as the handler for this signal.

Some of the execution environment for signal handlers is unpredictable; notably, the only library function required to work correctly from within a signal handler is signal itself, and only when used to redefine the handler for the current signal value.

Static storage is likewise unreliable for signal handlers, with one exception: if you declare a static storage location as 'volatile sig\_atomic\_t', then you may use that location in a signal handler to store signal values.

If your signal handler terminates using return (or implicit return), your program's execution continues at the point where it was when the signal was raised (whether by your program itself, or by an external event). Signal handlers can also use functions such as exit and abort to avoid returning.

The alternate function \_signal\_r is the reentrant version. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

If your request for a signal handler cannot be honored, the result is SIG\_ERR; a specific error number is also recorded in error.

Otherwise, the result is the previous handler (a function pointer or one of the predefined macros).

#### **Portability**

ANSI C requires signal.

No supporting OS subroutines are required to link with signal, but it will not have any useful effects, except for software generated signals, without an operating system that can actually raise exceptions.

# 8 Time Functions ('time.h')

This chapter groups functions used either for reporting on time (elapsed, current, or compute time) or to perform calculations based on time.

The header file 'time.h' defines three types. clock\_t and time\_t are both used for representations of time particularly suitable for arithmetic. (In this implementation, quantities of type clock\_t have the highest resolution possible on your machine, and quantities of type time\_t resolve to seconds.) size\_t is also defined if necessary for quantities representing sizes.

'time.h' also defines the structure tm for the traditional representation of Gregorian calendar time as a series of numbers, with the following fields:

tm\_sec Seconds, between 0 and 60 inclusive (60 allows for leap seconds).

tm\_min Minutes, between 0 and 59 inclusive.

tm\_hour Hours, between 0 and 23 inclusive.

tm\_mday Day of the month, between 1 and 31 inclusive.

tm\_mon Month, between 0 (January) and 11 (December).

tm\_year Year (since 1900), can be negative for earlier years.

tm\_wday Day of week, between 0 (Sunday) and 6 (Saturday).

tm\_yday Number of days elapsed since last January 1, between 0 and 365 inclusive.

tm\_isdst Daylight Savings Time flag: positive means DST in effect, zero means DST not in effect, negative means no information about DST is available. Although for

mktime(), negative means that it should decide if DST is in effect or not.

# 8.1 asctime—format time as string

# **Synopsis**

```
#include <time.h>
char *asctime(const struct tm *clock);
char *_asctime_r(const struct tm *clock, char *buf);
```

# Description

Format the time value at *clock* into a string of the form

```
Wed Jun 15 11:38:07 1988\n\0
```

The string is generated in a static buffer; each call to asctime overwrites the string generated by previous calls.

#### Returns

A pointer to the string containing a formatted timestamp.

# Portability

ANSI C requires asctime.

asctime requires no supporting OS subroutines.

# 8.2 clock—cumulative processor time

# **Synopsis**

```
#include <time.h>
clock_t clock(void);
```

## Description

Calculates the best available approximation of the cumulative amount of time used by your program since it started. To convert the result into seconds, divide by the macro CLOCKS\_PER\_SEC.

#### Returns

The amount of processor time used so far by your program, in units defined by the machine-dependent macro CLOCKS\_PER\_SEC. If no measurement is available, the result is (clock\_t)-1.

# Portability

ANSI C requires clock and CLOCKS\_PER\_SEC.

Supporting OS subroutine required: times.

# 8.3 ctime—convert time to local and format as string

### **Synopsis**

```
#include <time.h>
char *ctime(const time_t *clock);
char *ctime_r(const time_t *clock, char *buf);
```

## Description

Convert the time value at *clock* to local time (like localtime) and format it into a string of the form

```
\label{like 3.1} \begin{tabular}{ll} Wed Jun 15 11:38:07 1988\\ \ndots (like asctime). \end{tabular}
```

#### Returns

A pointer to the string containing a formatted timestamp.

# Portability

ANSI C requires ctime.

ctime requires no supporting OS subroutines.

# 8.4 difftime—subtract two times

# **Synopsis**

```
#include <time.h>
double difftime(time_t tim1, time_t tim2);
```

## Description

Subtracts the two times in the arguments: 'tim1 - tim2'.

#### Returns

The difference (in seconds) between tim2 and tim1, as a double.

# Portability

ANSI C requires difftime, and defines its result to be in seconds in all implementations. difftime requires no supporting OS subroutines.

# 8.5 gmtime—convert time to UTC traditional form

# **Synopsis**

```
#include <time.h>
struct tm *gmtime(const time_t *clock);
struct tm *gmtime_r(const time_t *clock, struct tm *res);
```

#### Description

gmtime takes the time at *clock* representing the number of elapsed seconds since 00:00:00 on January 1, 1970, Universal Coordinated Time (UTC, also known in some countries as GMT, Greenwich Mean time) and converts it to a struct tm representation.

gmtime constructs the traditional time representation in static storage; each call to gmtime or localtime will overwrite the information generated by previous calls to either function.

#### Returns

A pointer to the traditional time representation (struct tm).

#### **Portability**

ANSI C requires gmtime.

gmtime requires no supporting OS subroutines.

# 8.6 localtime—convert time to local representation

# **Synopsis**

```
#include <time.h>
struct tm *localtime(time_t *clock);
struct tm *localtime_r(time_t *clock, struct tm *res);
```

#### Description

localtime converts the time at *clock* into local time, then converts its representation from the arithmetic representation to the traditional representation defined by **struct tm**.

localtime constructs the traditional time representation in static storage; each call to gmtime or localtime will overwrite the information generated by previous calls to either function.

mktime is the inverse of localtime.

#### Returns

A pointer to the traditional time representation (struct tm).

## Portability

ANSI C requires localtime.

localtime requires no supporting OS subroutines.

# 8.7 mktime—convert time to arithmetic representation

### **Synopsis**

```
#include <time.h>
time_t mktime(struct tm *timp);
```

#### Description

mktime assumes the time at *timp* is a local time, and converts its representation from the traditional representation defined by struct tm into a representation suitable for arithmetic. localtime is the inverse of mktime.

#### Returns

If the contents of the structure at *timp* do not form a valid calendar time representation, the result is -1. Otherwise, the result is the time, converted to a time\_t value.

# Portability

ANSI C requires mktime.

mktime requires no supporting OS subroutines.

# 8.8 strftime—convert date and time to a formatted string Synopsis

#### Description

strftime converts a struct tm representation of the time (at timp) into a null-terminated string, starting at s and occupying no more than maxsize characters.

You control the format of the output using the string at format. \*format can contain two kinds of specifications: text to be copied literally into the formatted string, and time conversion specifications. Time conversion specifications are two- and three-character sequences beginning with '%' (use '%%' to include a percent sign in the output). Each defined conversion specification selects only the specified field(s) of calendar time data from \*timp, and converts it to a string in one of the following ways:

- The abbreviated weekday name according to the current locale. [tm\_wday]

  The full weekday name according to the current locale. In the default "C" locale, one of 'Sunday', 'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday', 'Saturday'. [tm\_wday]

  The abbreviated month name according to the current locale. [tm\_mon]
- The full month name according to the current locale. In the default "C" locale, one of 'January', 'February', 'March', 'April', 'May', 'June', 'July', 'August', 'September', 'October', 'November', 'December'. [tm\_mon]
- %c The preferred date and time representation for the current locale. [tm\_sec, tm\_min, tm\_hour, tm\_mday, tm\_mon, tm\_year, tm\_wday]
- The century, that is, the year divided by 100 then truncated. For 4-digit years, the result is zero-padded and exactly two characters; but for other years, there may a negative sign or more digits. In this way, '%C%y' is equivalent to '%Y'. [tm\_year]
- %d The day of the month, formatted with two digits (from '01' to '31'). [tm\_mday]
- %D A string representing the date, in the form "\m/\%d/\%y". [tm\_mday, tm\_mon, tm\_year]
- %e The day of the month, formatted with leading space if single digit (from '1' to '31'). [tm\_mday]
- %Ex In some locales, the E modifier selects alternative representations of certain modifiers x. In newlib, it is ignored, and treated as %x.
- %F A string representing the ISO 8601:2000 date format, in the form '"%Y-%m-%d"'. [tm\_mday, tm\_mon, tm\_year]
- %g The last two digits of the week-based year, see specifier %G (from '00' to '99').  $[tm\_year, tm\_wday, tm\_yday]$

- The week-based year. In the ISO 8601:2000 calendar, week 1 of the year includes January 4th, and begin on Mondays. Therefore, if January 1st, 2nd, or 3rd falls on a Sunday, that day and earlier belong to the last week of the previous year; and if December 29th, 30th, or 31st falls on Monday, that day and later belong to week 1 of the next year. For consistency with %Y, it always has at least four characters. Example: "%G" for Saturday 2nd January 1999 gives "1998", and for Tuesday 30th December 1997 gives "1998". [tm\_year, tm\_wday, tm\_yday]
- %h Synonym for "%b". [tm\_mon]
- %H The hour (on a 24-hour clock), formatted with two digits (from '00' to '23'). [tm\_hour]
- The hour (on a 12-hour clock), formatted with two digits (from '01' to '12'). [tm\_hour]
- %j The count of days in the year, formatted with three digits (from '001' to '366').

  [tm\_yday]
- %k The hour (on a 24-hour clock), formatted with leading space if single digit (from '0' to '23'). Non-POSIX extension (c.p. %I). [tm\_hour]
- The hour (on a 12-hour clock), formatted with leading space if single digit (from '1' to '12'). Non-POSIX extension (c.p. %H). [tm\_hour]
- The month number, formatted with two digits (from '01' to '12'). [tm\_mon]
- %M The minute, formatted with two digits (from '00' to '59'). [tm\_min]
- %n A newline character (' $\n'$ ).
- %0x In some locales, the O modifier selects alternative digit characters for certain modifiers x. In newlib, it is ignored, and treated as %x.
- %p Either 'AM' or 'PM' as appropriate, or the corresponding strings for the current locale. [tm\_hour]
- %P Same as '%p', but in lowercase. This is a GNU extension. [tm\_hour]
- %r Replaced by the time in a.m. and p.m. notation. In the "C" locale this is equivalent to "%I:%M:%S %p". In locales which don't define a.m./p.m. notations, the result is an empty string. [tm\_sec, tm\_min, tm\_hour]
- The 24-hour time, to the minute. Equivalent to "%H:%M". [tm\_min, tm\_hour]
- %S The second, formatted with two digits (from '00' to '60'). The value 60 accounts for the occasional leap second. [tm\_sec]
- %t A tab character ('\t').
- The 24-hour time, to the second. Equivalent to "%H:%M:%S". [tm\_sec, tm\_min, tm\_hour]
- "%u The weekday as a number, 1-based from Monday (from '1' to '7'). [tm\_wday]
- "WU The week number, where weeks start on Sunday, week 1 contains the first Sunday in a year, and earlier days are in week 0. Formatted with two digits (from '00' to '53'). See also "W. [tm\_wday, tm\_yday]

%V	The week number, where weeks start on Monday, week 1 contains January 4th,
	and earlier days are in the previous year. Formatted with two digits (from '01'
	to '53'). See also %G. [tm_year, tm_wday, tm_yday]
%w	The weekday as a number, 0-based from Sunday (from '0' to '6'). $[tm\_wday]$

W The week number, where weeks start on Monday, week 1 contains the first Monday in a year, and earlier days are in week 0. Formatted with two digits (from '00' to '53'). [tm\_wday, tm\_yday]

%x Replaced by the preferred date representation in the current locale. In the "C" locale this is equivalent to "%m/%d/%y". [tm\_mon, tm\_mday, tm\_year]

%X Replaced by the preferred time representation in the current locale. In the "C" locale this is equivalent to "%H:%M:%S". [tm\_sec, tm\_min, tm\_hour]

%y The last two digits of the year (from '00' to '99'). [tm\_year] (Implementation interpretation: always positive, even for negative years.)

"Y" The full year, equivalent to "C"y. It will always have at least four characters, but may have more. The year is accurate even when tm\_year added to the offset of 1900 overflows an int. [tm\_year]

The offset from UTC. The format consists of a sign (negative is west of Greewich), two characters for hour, then two characters for minutes (-hhmm or +hhmm). If tm\_isdst is negative, the offset is unknown and no output is generated; if it is zero, the offset is the standard offset for the current time zone; and if it is positive, the offset is the daylight savings offset for the current timezone. The offset is determined from the TZ environment variable, as if by calling tzset(). [tm\_isdst]

The time zone name. If tm\_isdst is negative, no output is generated. Otherwise, the time zone name is based on the TZ environment variable, as if by calling tzset(). [tm\_isdst]

%% A single character, '%'.

#### Returns

When the formatted time takes up no more than maxsize characters, the result is the length of the formatted string. Otherwise, if the formatting operation was abandoned due to lack of room, the result is 0, and the string starting at s corresponds to just those parts of \*format that could be completely filled in within the maxsize limit.

# Portability

ANSI C requires strftime, but does not specify the contents of \*s when the formatted string would require more than maxsize characters. Unrecognized specifiers and fields of timp that are out of range cause undefined results. Since some formats expand to 0 bytes, it is wise to set \*s to a nonzero value beforehand to distinguish between failure and an empty string. This implementation does not support s being NULL, nor overlapping s and format.

strftime requires no supporting OS subroutines.

# Bugs

 $\tt strftime$  ignores the LC\_TIME category of the current locale, hard-coding the "C" locale settings.

## 8.9 time—get current calendar time (as single number)

#### **Synopsis**

```
#include <time.h>
time_t time(time_t *t);
```

#### Description

time looks up the best available representation of the current time and returns it, encoded as a time\_t. It stores the same value at t unless the argument is NULL.

#### Returns

A -1 result means the current time is not available; otherwise the result represents the current time.

#### Portability

ANSI C requires time.

Supporting OS subroutine required: Some implementations require gettimeofday.

# 8.10 \_\_tz\_lock, \_\_tz\_unlock—lock time zone global variables Synopsis

```
#include "local.h"
void __tz_lock (void);
void __tz_unlock (void);
```

#### Description

The tzset facility functions call these functions when they need to ensure the values of global variables. The version of these routines supplied in the library use the lock API defined in sys/lock.h. If multiple threads of execution can call the time functions and give up scheduling in the middle, then you you need to define your own versions of these functions in order to safely lock the time zone variables during a call. If you do not, the results of localtime, mktime, ctime, and strftime are undefined.

The lock \_\_tz\_lock may not be called recursively; that is, a call \_\_tz\_lock will always lock all subsequent \_\_tz\_lock calls until the corresponding \_\_tz\_unlock call on the same thread is made.

# 8.11 tzset—set timezone characteristics from TZ environment variable

#### **Synopsis**

```
#include <time.h>
void tzset(void);
void _tzset_r (struct _reent *);
```

#### Description

tzset examines the TZ environment variable and sets up the three external variables: \_timezone, \_daylight, and tzname. The value of \_timezone shall be the offset from the current time zone to GMT. The value of \_daylight shall be 0 if there is no daylight savings time for the current time zone, otherwise it will be non-zero. The tzname array has two entries: the first is the name of the standard time zone, the second is the name of the daylight-savings time zone.

The TZ environment variable is expected to be in the following POSIX format: stdoffset1[dst[offset2][,start[/time1],end[/time2]]]

where: std is the name of the standard time-zone (minimum 3 chars) offset1 is the value to add to local time to arrive at Universal time it has the form: hh[:mm[:ss]] dst is the name of the alternate (daylight-savings) time-zone (min 3 chars) offset2 is the value to add to local time to arrive at Universal time it has the same format as the std offset start is the day that the alternate time-zone starts time1 is the optional time that the alternate time-zone starts (this is in local time and defaults to 02:00:00 if not specified) end is the day that the alternate time-zone ends time2 is the time that the alternate time-zone ends (it is in local time and defaults to 02:00:00 if not specified)

Note that there is no white-space padding between fields. Also note that if TZ is null, the default is Universal GMT which has no daylight-savings time. If TZ is empty, the default EST5EDT is used.

The function \_tzset\_r is identical to tzset only it is reentrant and is used for applications that use multiple threads.

#### Returns

There is no return value.

#### **Portability**

tzset is part of the POSIX standard.

Supporting OS subroutine required: None

## 9 Locale ('locale.h')

A locale is the name for a collection of parameters (affecting collating sequences and formatting conventions) that may be different depending on location or culture. The "C" locale is the only one defined in the ANSI C standard.

This is a minimal implementation, supporting only the required "C" value for locale; strings representing other locales are not honored. ("" is also accepted; it represents the default locale for an implementation, here equivalent to "C".

'locale.h' defines the structure lconv to collect the information on a locale, with the following fields:

#### char \*decimal\_point

The decimal point character used to format "ordinary" numbers (all numbers except those referring to amounts of money). "." in the C locale.

#### char \*thousands\_sep

The character (if any) used to separate groups of digits, when formatting ordinary numbers. "" in the C locale.

#### char \*grouping

Specifications for how many digits to group (if any grouping is done at all) when formatting ordinary numbers. The *numeric value* of each character in the string represents the number of digits for the next group, and a value of 0 (that is, the string's trailing NULL) means to continue grouping digits using the last value specified. Use CHAR\_MAX to indicate that no further grouping is desired. "" in the C locale.

#### char \*int\_curr\_symbol

The international currency symbol (first three characters), if any, and the character used to separate it from numbers. "" in the C locale.

#### char \*currency\_symbol

The local currency symbol, if any. "" in the C locale.

#### char \*mon\_decimal\_point

The symbol used to delimit fractions in amounts of money. "" in the C locale.

#### char \*mon\_thousands\_sep

Similar to thousands\_sep, but used for amounts of money. "" in the C locale.

#### char \*mon\_grouping

Similar to grouping, but used for amounts of money. "" in the C locale.

#### char \*positive\_sign

A string to flag positive amounts of money when formatting. "" in the C locale.

#### char \*negative\_sign

A string to flag negative amounts of money when formatting. "" in the C locale.

#### char int\_frac\_digits

The number of digits to display when formatting amounts of money to international conventions. CHAR\_MAX (the largest number representable as a char) in the C locale.

#### char frac\_digits

The number of digits to display when formatting amounts of money to local conventions. CHAR\_MAX in the C locale.

#### char p\_cs\_precedes

1 indicates the local currency symbol is used before a *positive or zero* formatted amount of money; 0 indicates the currency symbol is placed after the formatted number. CHAR\_MAX in the C locale.

#### char p\_sep\_by\_space

1 indicates the local currency symbol must be separated from *positive or zero* numbers by a space; 0 indicates that it is immediately adjacent to numbers. CHAR\_MAX in the C locale.

#### char n\_cs\_precedes

1 indicates the local currency symbol is used before a negative formatted amount of money; 0 indicates the currency symbol is placed after the formatted number. CHAR\_MAX in the C locale.

#### char n\_sep\_by\_space

1 indicates the local currency symbol must be separated from *negative* numbers by a space; 0 indicates that it is immediately adjacent to numbers. CHAR\_MAX in the C locale.

#### char p\_sign\_posn

Controls the position of the *positive* sign for numbers representing money. O means parentheses surround the number; 1 means the sign is placed before both the number and the currency symbol; 2 means the sign is placed after both the number and the currency symbol; 3 means the sign is placed just before the currency symbol; and 4 means the sign is placed just after the currency symbol. CHAR\_MAX in the C locale.

#### char n\_sign\_posn

Controls the position of the *negative* sign for numbers representing money, using the same rules as p\_sign\_posn. CHAR\_MAX in the C locale.

## 9.1 setlocale, localeconv—select or query locale

#### **Synopsis**

```
#include <locale.h>
char *setlocale(int category, const char *locale);
lconv *localeconv(void);

char *_setlocale_r(void *reent,
        int category, const char *locale);
lconv *_localeconv_r(void *reent);
```

#### Description

setlocale is the facility defined by ANSI C to condition the execution environment for international collating and formatting information; localeconv reports on the settings of the current locale.

This is a minimal implementation, supporting only the required "POSIX" and "C" values for locale; strings representing other locales are not honored unless \_MB\_CAPABLE is defined.

If \_MB\_CAPABLE is defined, POSIX locale strings are allowed, following the form language[\_TERRITORY][.charset][@modifier]

"language" is a two character string per ISO 639, or, if not available for a given language, a three character string per ISO 639-3. "TERRITORY" is a country code per ISO 3166. For "charset" and "modifier" see below.

Additionally to the POSIX specifier, the following extension is supported for backward compatibility with older implementations using newlib: "C-charset". Instead of "C-", you can also specify "C.". Both variations allow to specify language neutral locales while using other charsets than ASCII, for instance "C.UTF-8", which keeps all settings as in the C locale, but uses the UTF-8 charset.

The following charsets are recognized: "UTF-8", "JIS", "EUCJP", "SJIS", "K018-R", "K018-U", "GEORGIAN-PS", "PT154", "TIS-620", "IS0-8859-x" with  $1 \le x \le 16$ , or "CPxxx" with xxx in [437, 720, 737, 775, 850, 852, 855, 857, 858, 862, 866, 874, 932, 1125, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258].

Charsets are case insensitive. For instance, "EUCJP" and "eucJP" are equivalent. Charset names with dashes can also be written without dashes, as in "UTF8", "iso88591" or "koi8r". "EUCJP" and "EUCKR" are also recognized with dash, "EUC-JP" and "EUC-KR".

Full support for all of the above charsets requires that newlib has been build with multibyte support and support for all ISO and Windows Codepage. Otherwise all singlebyte charsets are simply mapped to ASCII. Right now, only newlib for Cygwin is built with full charset support by default. Under Cygwin, this implementation additionally supports the charsets "GBK", "GB2312", "eucCN", "eucKR", and "Big5". Cygwin does not support "JIS".

Cygwin additionally supports locales from the file /usr/share/locale/locale.alias.

("" is also accepted; if given, the settings are read from the corresponding  $LC_-$ \* environment variables and \$LANG according to POSIX rules.

This implementation also supports the modifier "cjknarrow", which affects how the functions wcwidth and wcswidth handle characters from the "CJK Ambiguous Width" category of characters described at http://www.unicode.org/reports/tr11/#Ambiguous. These

characters have a width of 1 for singlebyte charsets and a width of 2 for multibyte charsets other than UTF-8. For UTF-8, their width depends on the language specifier: it is 2 for "zh" (Chinese), "ja" (Japanese), and "ko" (Korean), and 1 for everything else. Specifying "cjknarrow" forces a width of 1, independent of charset and language.

If you use NULL as the *locale* argument, setlocale returns a pointer to the string representing the current locale. The acceptable values for *category* are defined in 'locale.h' as macros beginning with "LC\_".

localeconv returns a pointer to a structure (also defined in 'locale.h') describing the locale-specific conventions currently in effect.

\_localeconv\_r and \_setlocale\_r are reentrant versions of localeconv and setlocale respectively. The extra argument reent is a pointer to a reentrancy structure.

#### Returns

A successful call to setlocale returns a pointer to a string associated with the specified category for the new locale. The string returned by setlocale is such that a subsequent call using that string will restore that category (or all categories in case of LC\_ALL), to that state. The application shall not modify the string returned which may be overwritten by a subsequent call to setlocale. On error, setlocale returns NULL.

localeconv returns a pointer to a structure of type lconv, which describes the formatting and collating conventions in effect (in this implementation, always those of the C locale).

#### **Portability**

ANSI C requires setlocale, but the only locale required across all implementations is the C locale.

## 10 Reentrancy

Reentrancy is a characteristic of library functions which allows multiple processes to use the same address space with assurance that the values stored in those spaces will remain constant between calls. The Red Hat newlib implementation of the library functions ensures that whenever possible, these library functions are reentrant. However, there are some functions that can not be trivially made reentrant. Hooks have been provided to allow you to use these functions in a fully reentrant fashion.

These hooks use the structure \_reent defined in 'reent.h'. A variable defined as 'struct \_reent' is called a reentrancy structure. All functions which must manipulate global information are available in two versions. The first version has the usual name, and uses a single global instance of the reentrancy structure. The second has a different name, normally formed by prepending '\_' and appending '\_r', and takes a pointer to the particular reentrancy structure to use.

For example, the function fopen takes two arguments, file and mode, and uses the global reentrancy structure. The function \_fopen\_r takes the arguments, struct\_reent, which is a pointer to an instance of the reentrancy structure, file and mode.

There are two versions of 'struct\_reent', a normal one and one for small memory systems, controlled by the \_REENT\_SMALL definition from the (automatically included) '<sys/config.h>'.

Each function which uses the global reentrancy structure uses the global variable <u>\_impure\_</u> ptr, which points to a reentrancy structure.

This means that you have two ways to achieve reentrancy. Both require that each thread of execution control initialize a unique global variable of type 'struct \_reent':

- 1. Use the reentrant versions of the library functions, after initializing a global reentrancy structure for each process. Use the pointer to this structure as the extra argument for all library functions.
- 2. Ensure that each thread of execution control has a pointer to its own unique reentrancy structure in the global variable \_impure\_ptr, and call the standard library subroutines.

The following functions are provided in both reentrant and non-reentrant versions.

Equivalent for errno variable:

```
_errno_r

Locale functions:
    _localeconv_r _setlocale_r

Equivalents for stdio variables:
    _stdin_r _stdout_r _stderr_r
```

```
Stdio functions:
    _fdopen_r
                     _perror_r
                                     _tempnam_r
                                     _tmpnam_r
    _fopen_r
                     _putchar_r
                     _puts_r
                                     _tmpfile_r
     _getchar_r
                                     _vfprintf_r
     _gets_r
                     _remove_r
                                     _vsnprintf_r
     _iprintf_r
                     _rename_r
     _mkstemp_r
                     _snprintf_r
                                     _vsprintf_r
     _mktemp_t
                     _sprintf_r
Signal functions:
     _init_signal_r _signal_r
     _kill_r
                     __sigtramp_r
     _raise_r
Stdlib functions:
    _calloc_r
                     _mblen_r
                                     _setenv_r
                     _mbstowcs_r
                                     _srand_r
     _dtoa_r
    _free_r
                    _mbtowc_r
                                     _strtod_r
    _getenv_r
                                     _strtol_r
                    _memalign_r
     _mallinfo_r
                    _mstats_r
                                     _strtoul_r
     _malloc_r
                                     _system_r
                     _putenv_r
     _malloc_r
                     _rand_r
                                     _wcstombs_r
     _malloc_stats_r _realloc_r
                                     _wctomb_r
String functions:
     _strdup_r
                     _strtok_r
System functions:
    _close_r
                     _link_r
                                     _unlink_r
                     _lseek_r
    _execve_r
                                     _wait_r
     _fcntl_r
                     _open_r
                                     _write_r
     _fork_r
                     _read_r
                     _sbrk_r
     _fstat_r
     _gettimeofday_r _stat_r
     _getpid_r
                     _times_r
Time function:
```

\_asctime\_r

## 11 Miscellaneous Macros and Functions

This chapter describes miscellaneous routines not covered elsewhere.

## 11.1 ffs—find first bit set in a word

#### **Synopsis**

```
#include <strings.h>
int ffs(int word);
```

## Description

ffs returns the first bit set in a word.

#### Returns

ffs returns 0 if c is 0, 1 if c is odd, 2 if c is a multiple of 2, etc.

## Portability

ffs is not ANSI C.

No supporting OS subroutines are required.

## 11.2 unctrl—get printable representation of a character

#### **Synopsis**

```
#include <unctrl.h>
char *unctrl(int c);
int unctrllen(int c);
```

#### Description

unctrl is a macro which returns the printable representation of c as a string. unctrllen is a macro which returns the length of the printable representation of c.

#### Returns

unctrl returns a string of the printable representation of c. unctrllen returns the length of the string which is the printable representation of c.

#### Portability

unctrl and unctrllen are not ANSI C.

No supporting OS subroutines are required.

## 12 System Calls

The C subroutine library depends on a handful of subroutine calls for operating system services. If you use the C library on a system that complies with the POSIX.1 standard (also known as IEEE 1003.1), most of these subroutines are supplied with your operating system.

If some of these subroutines are not provided with your system—in the extreme case, if you are developing software for a "bare board" system, without an OS—you will at least need to provide do-nothing stubs (or subroutines with minimal functionality) to allow your programs to link with the subroutines in libc.a.

#### 12.1 Definitions for OS interface

This is the complete set of system definitions (primarily subroutines) required; the examples shown implement the minimal functionality required to allow libc to link, and fail gracefully where OS services are not available.

Graceful failure is permitted by returning an error code. A minor complication arises here: the C library must be compatible with development environments that supply fully functional versions of these subroutines. Such environments usually return error codes in a global errno. However, the Red Hat newlib C library provides a *macro* definition for errno in the header file 'errno.h', as part of its support for reentrant routines (see Chapter 10 [Reentrancy], page 295).

The bridge between these two interpretations of errno is straightforward: the C library routines with OS interface calls capture the errno values returned globally, and record them in the appropriate field of the reentrancy structure (so that you can query them using the errno macro from 'errno.h').

This mechanism becomes visible when you write stub routines for OS interfaces. You must include 'errno.h', then disable the macro, like this:

```
#include <errno.h>
#undef errno
extern int errno;
```

The examples in this chapter include this treatment of errno.

\_exit Exit a program without cleaning up files. If your system doesn't provide this, it is best to avoid linking with subroutines that require it (exit, system).

close Close a file. Minimal implementation:

```
int close(int file) {
  return -1;
}
```

environ A pointer to a list of environment variables and their values. For a minimal environment, this empty list is adequate:

```
char *__env[1] = { 0 };
char **environ = __env;
```

execve Transfer control to a new process. Minimal implementation (for a system without processes):

```
#include <errno.h>
                #undef errno
                extern int errno;
                int execve(char *name, char **argv, char **env) {
                   errno = ENOMEM;
                   return -1;
                }
fork
           Create a new process. Minimal implementation (for a system without pro-
           cesses):
                #include <errno.h>
                #undef errno
                extern int errno;
                int fork(void) {
                   errno = EAGAIN;
                   return -1;
           Status of an open file. For consistency with other minimal implementations
fstat
           in these examples, all files are regarded as character special devices.
           'sys/stat.h' header file required is distributed in the 'include' subdirectory
           for this C library.
                #include <sys/stat.h>
                int fstat(int file, struct stat *st) {
                   st->st_mode = S_IFCHR;
                   return 0;
                }
           Process-ID; this is sometimes used to generate strings unlikely to conflict with
getpid
           other processes. Minimal implementation, for a system without processes:
                int getpid(void) {
                   return 1;
                }
           Query whether output stream is a terminal. For consistency with the other
isatty
           minimal implementations, which only support output to stdout, this minimal
           implementation is suggested:
                int isatty(int file) {
                   return 1;
```

kill Send a signal. Minimal implementation:

#include <errno.h>

#undef errno

}

#undef errno
extern int errno;
int kill(int pid, int sig) {
 errno = EINVAL;
 return -1;
}

```
link
           Establish a new name for an existing file. Minimal implementation:
                #include <errno.h>
                #undef errno
                extern int errno;
                int link(char *old, char *new) {
                  errno = EMLINK;
                  return -1;
                }
lseek
           Set position in a file. Minimal implementation:
                int lseek(int file, int ptr, int dir) {
                  return 0;
                }
           Open a file. Minimal implementation:
open
                int open(const char *name, int flags, int mode) {
                  return -1;
                }
read
           Read from a file. Minimal implementation:
                int read(int file, char *ptr, int len) {
                  return 0;
                }
sbrk
           Increase program data space. As malloc and related functions depend on this,
           it is useful to have a working implementation. The following suffices for a
           standalone system; it exploits the symbol _end automatically defined by the
           GNU linker.
                caddr_t sbrk(int incr) {
                  extern char _end; /* Defined by the linker */
                  static char *heap_end;
                  char *prev_heap_end;
                  if (heap\_end == 0) {
                    heap_end = &_end;
                  prev_heap_end = heap_end;
                  if (heap_end + incr > stack_ptr) {
                    write (1, "Heap and stack collision\n", 25);
                    abort ();
                  }
                  heap_end += incr;
                  return (caddr_t) prev_heap_end;
stat
           Status of a file (by name). Minimal implementation:
                int stat(char *file, struct stat *st) {
```

```
st->st_mode = S_IFCHR;
                  return 0;
                }
           Timing information for current process. Minimal implementation:
times
                int times(struct tms *buf) {
                  return -1;
                }
unlink
           Remove a file's directory entry. Minimal implementation:
                #include <errno.h>
                #undef errno
                extern int errno;
                int unlink(char *name) {
                  errno = ENOENT;
                  return -1;
           Wait for a child process. Minimal implementation:
wait
                #include <errno.h>
                #undef errno
                extern int errno;
                int wait(int *status) {
                  errno = ECHILD;
                  return -1;
                }
write
```

Write to a file. 'libc' subroutines will use this system routine for output to all files, including stdout—so if you need to generate any output, for example to a serial port for debugging, you should make your minimal write capable of doing this. The following minimal implementation is an incomplete example; it relies on a outbyte subroutine (not shown; typically, you must write this in assembler from examples provided by your hardware manufacturer) to actually perform the output.

```
int write(int file, char *ptr, int len) {
  int todo;

for (todo = 0; todo < len; todo++) {
   outbyte (*ptr++);
  }
  return len;
}</pre>
```

## 12.2 Reentrant covers for OS subroutines

Since the system subroutines are used by other library routines that require reentrancy, 'libc.a' provides cover routines (for example, the reentrant version of fork is \_fork\_r). These cover routines are consistent with the other reentrant subroutines in this library, and achieve reentrancy by using a reserved global data block (see Chapter 10 [Reentrancy], page 295).

\_open\_r A reentrant version of open. It takes a pointer to the global data block, which holds errno.

```
int _open_r(void *reent,
    const char *file, int flags, int mode);
```

\_close\_r A reentrant version of close. It takes a pointer to the global data block, which holds errno.

```
int _close_r(void *reent, int fd);
```

\_lseek\_r A reentrant version of lseek. It takes a pointer to the global data block, which holds errno.

```
off_t _lseek_r(void *reent,
    int fd, off_t pos, int whence);
```

\_read\_r A reentrant version of read. It takes a pointer to the global data block, which holds errno.

```
long _read_r(void *reent,
    int fd, void *buf, size_t cnt);
```

\_write\_r A reentrant version of write. It takes a pointer to the global data block, which holds errno.

```
long _write_r(void *reent,
   int fd, const void *buf, size_t cnt);
```

\_fork\_r A reentrant version of fork. It takes a pointer to the global data block, which holds errno.

```
int _fork_r(void *reent);
```

\_wait\_r A reentrant version of wait. It takes a pointer to the global data block, which holds errno.

```
int _wait_r(void *reent, int *status);
```

\_stat\_r A reentrant version of stat. It takes a pointer to the global data block, which holds errno.

```
int _stat_r(void *reent,
     const char *file, struct stat *pstat);
```

\_fstat\_r A reentrant version of fstat. It takes a pointer to the global data block, which holds errno.

```
int _fstat_r(void *reent,
   int fd, struct stat *pstat);
```

\_link\_r A reentrant version of link. It takes a pointer to the global data block, which holds errno.

```
int _link_r(void *reent,
    const char *old, const char *new);
```

\_unlink\_r

A reentrant version of unlink. It takes a pointer to the global data block, which holds errno.

```
int _unlink_r(void *reent, const char *file);
```

\_sbrk\_r A reentrant version of sbrk. It takes a pointer to the global data block, which holds errno.

```
char *_sbrk_r(void *reent, size_t incr);
```

## 13 Variable Argument Lists

The printf family of functions is defined to accept a variable number of arguments, rather than a fixed argument list. You can define your own functions with a variable argument list, by using macro definitions from either 'stdarg.h' (for compatibility with ANSI C) or from 'varargs.h' (for compatibility with a popular convention prior to ANSI C).

## 13.1 ANSI-standard macros, 'stdarg.h'

In ANSI C, a function has a variable number of arguments when its parameter list ends in an ellipsis (...). The parameter list must also include at least one explicitly named argument; that argument is used to initialize the variable list data structure.

ANSI C defines three macros (va\_start, va\_arg, and va\_end) to operate on variable argument lists. 'stdarg.h' also defines a special type to represent variable argument lists: this type is called va\_list.

#### 13.1.1 Initialize variable argument list

#### **Synopsis**

```
#include <stdarg.h>
void va_start(va_list ap, rightmost);
```

#### Description

Use va\_start to initialize the variable argument list ap, so that va\_arg can extract values from it. rightmost is the name of the last explicit argument in the parameter list (the argument immediately preceding the ellipsis '...' that flags variable arguments in an ANSI C function header). You can only use va\_start in a function declared using this ellipsis notation (not, for example, in one of its subfunctions).

#### Returns

va\_start does not return a result.

#### **Portability**

ANSI C requires va\_start.

#### 13.1.2 Extract a value from argument list

#### **Synopsis**

```
#include <stdarg.h>
type va_arg(va_list ap, type);
```

#### Description

va\_arg returns the next unprocessed value from a variable argument list ap (which you must previously create with va\_start). Specify the type for the value as the second parameter to the macro, type.

You may pass a va\_list object ap to a subfunction, and use va\_arg from the subfunction rather than from the function actually declared with an ellipsis in the header; however, in that case you may only use va\_arg from the subfunction. ANSI C does not permit extracting successive values from a single variable-argument list from different levels of the calling stack.

There is no mechanism for testing whether there is actually a next argument available; you might instead pass an argument count (or some other data that implies an argument count) as one of the fixed arguments in your function call.

#### Returns

va\_arg returns the next argument, an object of type type.

#### Portability

ANSI C requires va\_arg.

#### 13.1.3 Abandon a variable argument list

#### **Synopsis**

```
#include <stdarg.h>
void va_end(va_list ap);
```

#### Description

Use va\_end to declare that your program will not use the variable argument list ap any further.

#### Returns

va\_end does not return a result.

#### Portability

ANSI C requires va\_end.

## 13.2 Traditional macros, 'varargs.h'

If your C compiler predates ANSI C, you may still be able to use variable argument lists using the macros from the 'varargs.h' header file. These macros resemble their ANSI counterparts, but have important differences in usage. In particular, since traditional C has no declaration mechanism for variable argument lists, two additional macros are provided simply for the purpose of defining functions with variable argument lists.

As with 'stdarg.h', the type va\_list is used to hold a data structure representing a variable argument list.

## 13.2.1 Declare variable arguments

#### Synopsis

```
#include <varargs.h>
function(va_alist)
va_dcl
```

#### Description

To use the 'varargs.h' version of variable argument lists, you must declare your function with a call to the macro va\_alist as its argument list, and use va\_dcl as the declaration. Do not use a semicolon after va\_dcl.

#### Returns

These macros cannot be used in a context where a return is syntactically possible.

#### **Portability**

 $va\_alist$  and  $va\_dcl$  were the most widespread method of declaring variable argument lists prior to ANSI C.

## 13.2.2 Initialize variable argument list

#### Synopsis

```
#include <varargs.h>
va_list ap;
va_start(ap);
```

#### Description

With the 'varargs.h' macros, use va\_start to initialize a data structure ap to permit manipulating a variable argument list. ap must have the type va\_alist.

#### Returns

va\_start does not return a result.

#### **Portability**

va\_start is also defined as a macro in ANSI C, but the definitions are incompatible; the ANSI version has another parameter besides ap.

## 13.2.3 Extract a value from argument list

#### **Synopsis**

```
#include <varargs.h>
type va_arg(va_list ap, type);
```

#### Description

va\_arg returns the next unprocessed value from a variable argument list ap (which you must previously create with va\_start). Specify the type for the value as the second parameter to the macro, type.

#### Returns

va\_arg returns the next argument, an object of type type.

#### **Portability**

The va\_arg defined in 'varargs.h' has the same syntax and usage as the ANSI C version from 'stdarg.h'.

## 13.2.4 Abandon a variable argument list

#### **Synopsis**

```
#include <varargs.h>
va_end(va_list ap);
```

#### Description

Use  $va\_end$  to declare that your program will not use the variable argument list ap any further.

#### Returns

va\_end does not return a result.

#### **Portability**

The va\_end defined in 'varargs.h' has the same syntax and usage as the ANSI C version from 'stdarg.h'.

The body of this manual is set in cmr10 at 10.95pt, with headings in cmb10 at 10.95pt and examples in cmtt10 at 10.95pt. cmti10 at 10.95pt and cmsl10 at 10.95pt are used for emphasis.

## Table of Contents

1	In	troduction	1
<b>2</b>	St	candard Utility Functions ('stdlib.h')	3
	2.1	_Exit—end program execution with no cleanup processing	. 4
	2.2	a641, 164a—convert between radix-64 ASCII string and long	. 5
	2.3	abort—abnormal termination of a program	. 6
	2.4	abs—integer absolute value (magnitude)	. 7
	2.5	assert—macro for debugging diagnostics	. 8
	2.6	$\verb"atexit$—request execution of functions at program exit$	. 9
	2.7	atof, atoff—string to double or float	10
	2.8	atoi, atol—string to integer	11
	2.9	atoll—convert a string to a long long integer	12
	2.10	bsearch—binary search	13
	2.11	calloc—allocate space for arrays	14
	2.12	div—divide two integers	
	2.13	ecvt, ecvtf, fcvt, fcvtf—double or float to string	
	2.14	gvcvt, gcvtf—format double or float as string	
	2.15	ecvtbuf, fcvtbuf—double or float to string	
	2.16	env_lock,env_unlock—lock environ variable	
	2.17	exit—end program execution	
	2.18	getenv—look up environment variable	
	2.19	labs—long integer absolute value	
	2.20	ldiv—divide two long integers	
	2.21	11abs—compute the absolute value of an long long integer	
	2.22	11div—divide two long long integers	
	2.23	malloc, realloc, free—manage memory	
	2.24	mallinfo, malloc_stats, mallopt—malloc support	
	2.25 2.26	malloc_lock,malloc_unlock—lock malloc pool	
	2.20 $2.27$	mblen—minimal multibyte length function	30
		wide-character string	21
	2.28	mbstowcs—minimal multibyte string to wide char converter	
	2.29	mbtowc—minimal multibyte to wide char converter	
	2.30	on_exit—request execution of function with argument at	55
		program exit	34
	2.31		35
	2.32	rand, srand—pseudo-random numbers	
	2.33	rand48, drand48, erand48, lrand48, nrand48, mrand48,	00
		jrand48, srand48, seed48, lcong48—pseudo-random number	
		generators and initialization routines	37
	2.34	strtod, strtof—string to double or float	
	2.35	strtol—string to long	
	2.36	strtoll—string to long long	

	2.37	strtoul—string to unsigned long	44
	2.38	strtoull—string to unsigned long long	46
	2.39	wcsrtombs, wcsnrtombs—convert a wide-character string to a	
		character string	48
	2.40	wcstod, wcstof—wide char string to double or float	49
	2.41	wcstol—wide string to long	50
	2.42	wcstoll—wide string to long long	52
	2.43	wcstoul—wide string to unsigned long	54
	2.44		
	2.45	•	58
	2.46	wcstombs—minimal wide char string to multibyte string	
		converter	
	2.47	wctomb—minimal wide char to multibyte converter	60
3	$\mathbf{C}$	haracter Type Macros and Functions	
	(	('ctype.h')	61
	3.1	isalnum—alphanumeric character predicate	62
	3.2	isalpha—alphabetic character predicate	
	3.3	isascii—ASCII character predicate	
	3.4	iscntrl—control character predicate	
	3.5	isdigit—decimal digit predicate	
	3.6	islower—lowercase character predicate	
	3.7	isprint, isgraph—printable character predicates	68
	3.8	ispunct—punctuation character predicate	69
	3.9	isspace—whitespace character predicate	70
	3.10	isupper—uppercase character predicate	71
	3.11	isxdigit—hexadecimal digit predicate	
	3.12	toascii—force integers to ASCII range	
	3.13	tolower—translate characters to lowercase	
	3.14	11	
	3.15	iswalnum—alphanumeric wide character test	
	3.16	iswalpha—alphabetic wide character test	
	3.17	iswcntrl—control wide character test	
	3.18	iswblank—blank wide character test	
	3.19	iswdigit—decimal digit wide character test	
	3.20	iswgraph—graphic wide character test	
	3.21 3.22	iswlower—lowercase wide character test	
	3.23	iswpunct—punctuation wide character test	
	3.24	iswspace—whitespace wide character test	
	3.24 $3.25$	iswupper—uppercase wide character test	
	3.26	iswxdigit—hexadecimal digit wide character test	
	3.27	iswctype—extensible wide-character test	
	3.28	wctype—get wide-character classification type	
	3.29	towlower—translate wide characters to lowercase	
	3.30	towupper—translate wide characters to uppercase	
	3.31	towctrans—extensible wide-character translation	
	3.32		

4	In	put and Output ('stdio.h')	95
	4.1	clearerr—clear file or stream error indicator	. 96
	4.2	diprintf, vdiprintf—print to a file descriptor (integer only).	
	4.3	dprintf, vdprintf—print to a file descriptor	
	4.4	fclose—close a file	
	4.5	fcloseall—close all files	100
	4.6	fdopen—turn open file into a stream	101
	4.7	feof—test for end of file	
	4.8	ferror—test whether read/write error has occurred	103
	4.9	fflush—flush buffered file output	104
	4.10	fgetc—get a character from a file or stream	105
	4.11	fgetpos—record position in a stream or file	106
	4.12	fgets—get character string from a file or stream	107
	4.13	fgetwc, getwc—get a wide character from a file or stream	108
	4.14	fgetws—get wide character string from a file or stream	109
	4.15	fileno—return file descriptor associated with stream	110
	4.16	fmemopen—open a stream around a fixed-length string	111
	4.17	fopen—open a file	112
	4.18	fopencookie—open a stream with custom callbacks	114
	4.19	fpurge—discard pending file I/O	116
	4.20	fputc—write a character on a stream or file	117
	4.21	fputs—write a character string in a file or stream	118
	4.22	fputwc, putwc—write a wide character on a stream or file	119
	4.23	fputws—write a wide character string in a file or stream	120
	4.24	fread—read array elements from a file	121
	4.25	freopen—open a file using an existing file descriptor	
	4.26	fseek, fseeko—set file position	123
	4.27	fsetpos—restore position of a stream or file	124
	4.28	ftell, ftello—return position in a stream or file	
	4.29	funopen, fropen, fwopen—open a stream with custom callba	
	4.30		
	4.31		
	4.32	getc—read a character (macro)	
	4.33	getc_unlocked—non-thread-safe version of getc (macro)	
	4.34	getchar—read a character (macro)	
	4.35	getchar_unlocked—non-thread-safe version of getchar (macr	
	4.36	getdelim—read a line up to a specified line delimiter	
	4.37	getline—read a line from a file	
	4.38	gets—get character string (obsolete, use fgets instead)	
	4.39	getw—read a word (int)	
	4.40	getwchar—read a wide character from standard input	
	4.41	mktemp, mkstemp, mkstemps,	139
	4.42	open_memstream, open_wmemstream—open a write stream	
		around an arbitrary-length string	
	4.43	perror—print an error message on standard error	
	4.44	putc—write a character (macro)	143

4.45	<pre>putc_unlocked—non-thread-safe version of putc (macro)</pre>	144
4.46	putchar—write a character (macro)	145
4.47	putchar_unlocked—non-thread-safe version of putchar (macr	o)
		146
4.48	puts—write a character string	147
4.49	putw—write a word (int)	148
4.50	putwchar—write a wide character to standard output	149
4.51	remove—delete a file's name	150
4.52	rename—rename a file	151
4.53	rewind—reinitialize a file or stream	152
4.54	setbuf—specify full buffering for a file or stream	153
4.55	setbuffer—specify full buffering for a file or stream with size	
		154
4.56		155
4.57	1 0	156
4.58		
	1 ( 0 0)	157
4.59	, ,	
		158
4.60		
	asnprintf—format output	159
4.61	, , ,	165
4.62		1 =0
4 00		170
4.63		1 70
1 0 1	input	176
4.64	1 0	181
4.65	1 / 1	182
4.66	S 1	183
4.67	0 1	184
4.68		105
4 60	vasnprintf—format argument list	185
4.69	, ,	186
4.70	1 , 1 , 1	107
4 71	argument list	187
4.71	, ,	
1 70	from wide character input	188
4.72		100
1 79	• • • • • • • • • • • • • • • • • • • •	189
4.73	viscanf, vfiscanf, vsiscanf—format argument list	190

5.1	bcmp—compare two memory areas
5.2	bcopy—copy memory regions
5.3	bzero—initialize memory to zero
5.4	index—search for character in string
5.5	memccpy—copy memory regions with end-token check
5.6	memchr—find character in memory
5.7	memcmp—compare two memory areas
5.8	memcpy—copy memory regions
5.9	memmem—find memory segment
5.10	memmove—move possibly overlapping memory
5.11	mempcpy—copy memory regions and return end pointer
5.12	memset—set an area of memory
5.13	· ·
5.14	stpcpy—copy string returning a pointer to its end
5.15	stpncpy—counted copy string returning a pointer to its end
0.10	Counted copy string returning a pointer to the ond
5.16	strcasecmp—case-insensitive character string compare
5.17	strcasestr—case-insensitive character string search
5.18	strcat—concatenate strings
5.19	strchr—search for character in string
5.20	strcmp—character string compare
5.21	strcoll—locale-specific character string compare
5.22	strcpy—copy string
5.23	strcspn—count characters not in string
5.24	strerror—convert error number to string
5.24 $5.25$	strerror_r—convert error number to string and copy to bu
0.20	streif of a convert error number to string and copy to bu
5.26	strlen—character string length
5.27	9 9
5.28	strncasecmp—case-insensitive character string compare
5.29	strncat—concatenate strings
5.30	strncmp—character string compare
5.31	strncpy—counted copy string
5.32	strnlen—character string length
5.33	strpbrk—find characters in string
5.34	strrchr—reverse search for character in string
5.35	strsignal—convert signal number to string
5.36	strspn—find initial match
5.37	strstr—find string segment
5.38	strtok, strtok_r, strsep—get next token from a string
5.39	strupr—force string to uppercase
5.40	strxfrm—transform string
5.41	swab—swap adjacent bytes
5.41 $5.42$	wcscasecmp—case-insensitive wide character string compare
	webcaseomb case-insensitive wide character string compare
0.42	

5.44 wcsncasecmp	—case-insensitive wide character string comp	_
6 Wide Chara		
	cter Strings ('wchar.h')	
	a wide character in memory	
-	pare wide characters in memory	
= ·	y wide characters in memory	
_	py wide characters in memory with overlapp	
areas 6.5 wmemset—set v	wide characters in memory	
	atenate two wide-character strings	
	-character string scanning operation	
	pare two wide-character strings	
	de-specific wide-character string compare	
	y a wide-character string	
20	y a wide-character string returning a pointer	
end		
	t length of a complementary wide substring.	
1 0	nvert date and time to a formatted wide-cha	
		254
6.14 wcslcat—cor	ncatenate wide-character strings to specified	length
		255
$6.15$ wcslcpy— ${ m cop}$	py a wide-character string to specified length	1 256
6.16 wcslen—get	wide-character string length	257
6.17 wcsncat—cor	ncatenate part of two wide-character strings	258
6.18 wcsncmp—con	mpare part of two wide-character strings	$\dots 259$
	py part of a wide-character string	
	py part of a wide-character string returning a	
*	nd	
9	t fixed-size wide-character string length	
6.22 wcspbrk—-sca	an wide-character string for a wide-character	
	de-character string scanning operation	
	length of a wide substring	
	a wide-character substring	
	next token from a string	
	umber of column positions of a wide-charact	
	cale-specific wide-character string transforma	
	mber of column positions of a wide-character	
	inder of column positions of a wide-character	
		210
7 Signal Hand	lling ('signal.h')	271
7.1 psignal—prin	at a signal message on standard error	272
	ı signal	
7.3 signal—specif	fy handler subroutine for a signal	274

8 Time	Functions ('time.h') 275
8.1 asct	ime—format time as string
8.2 cloc	k—cumulative processor time
	e—convert time to local and format as string
	time—subtract two times
•	me—convert time to UTC traditional form
	1time—convert time to local representation
	me—convert time to arithmetic representation
	get current calendar time (as single number)
	z_lock,tz_unlock—lock time zone global variables 288
	et—set timezone characteristics from TZ environment
	289
9 Local	e ('locale.h') 291
	` '
9.1 set1	ocale, localeconv—select or query locale
10 Reei	ntrancy
11 Misc	cellaneous Macros and Functions 297
	—find first bit set in a word
	trl—get printable representation of a character
11.2 0.10	See printed to proceed of a character with the
12 Syst	em Calls 301
_	initions for OS interface
	ntrant covers for OS subroutines
19 Voni	able Angument Lists 207
	able Argument Lists 307
	SI-standard macros, 'stdarg.h'
	Initialize variable argument list
13.1.2	Extract a value from argument list
	ditional macros, 'varargs.h'
13.2.1	Declare variable arguments
13.2.2	Initialize variable argument list
13.2.3	Extract a value from argument list
13.2.4	Abandon a variable argument list
